# Logistics

## Reading Bryant/O'Hallaron

- ▶ Ch 4: Finish / Skim
- ▶ Ch 6: Memory

## Assignments

- ▶ Lab 11: `clock()` function
- ▶ HW 11: Memory Optimization
- ▶ P4: Overview Video Tue

## Goals

- ▶ Memory efficient programs
- ▶ Permanent Storage

## Schedule

Date	Event
Mon 11/22	Storage
Tue 11/23	P4 Overview Video
Wed 11/24	Micro Opt
	Lab: Preprocessor
Thu/Fri	Break
Mon 11/29	Micro Opt
Wed 12/01	Review
	Lab: Review
	<b>P4 Due</b>
Fri 12/03	<b>Exam 3</b>

# Architecture Performance

```
// LOOP 1
for(i=0; i<iters; i++){
    retA += delA;
    retB += delB;
}
*start = retA+retB;

// LOOP 2
for(i=0; i<iters; i++){
    retA += delA;
    retA += delB;
}
*start = retA;
```

- ▶ LOOP1 or LOOP2 faster?
- ▶ Why?

## Exercise: 2D Arrays

- ▶ Several ways to construct “2D” arrays in C
- ▶ All must *embed* a 2D construct into 1-dimensional memory
- ▶ Consider the 2 styles below: how will the picture of memory look different?

```
// REPEATED MALLOC
// allocate
int rows=100, cols=30;
int **mat =
    malloc(rows * sizeof(int*));

for(int i=0; i<rows; i++){
    mat[i] = malloc(cols*sizeof(int));
}

// do work
mat[i][j] = ...

// free memory
for(int i=0; i<rows; i++){
    free(mat[i]);
}
free(mat);
```

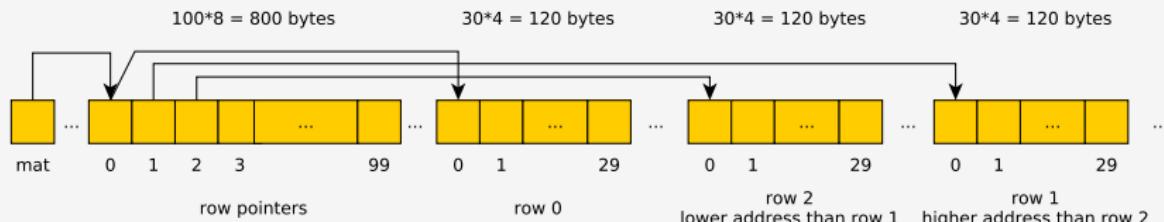

```
// TWO MALLOCs
// allocate
int rows=100, cols=30;
int **mat =
    malloc(rows * sizeof(int*));
int *data =
    malloc(rows*cols*sizeof(int));
for(int i=0; i<rows; i++){
    mat[i] = data+i*cols;
}

// do work
mat[i][j] = ...

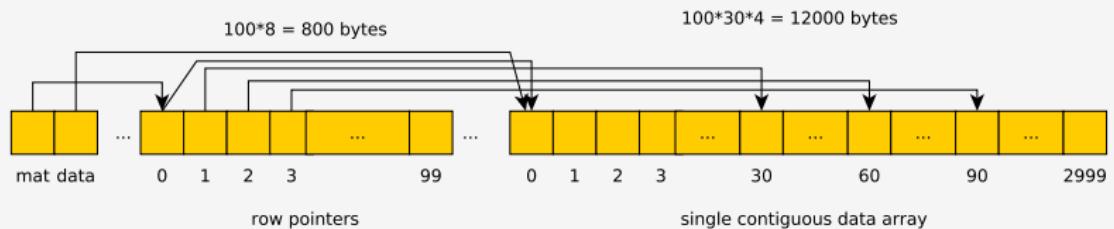

// free memory
free(data);
free(mat);
```

# Answer: 2D Arrays

## Repeated Mallocs

## Two Mallocs

# Single Malloc Matrices

Somewhat common to use a 1D array as a 2D matrix as in

```
int *matrix =
    malloc(rows*cols*sizeof(int));

int i=5, j=20;
int elem_ij = matrix[ i*cols + j ]; // retrieve element i,j
```

HW11/P4 will use this technique along with some structs and macros to make it more readable:

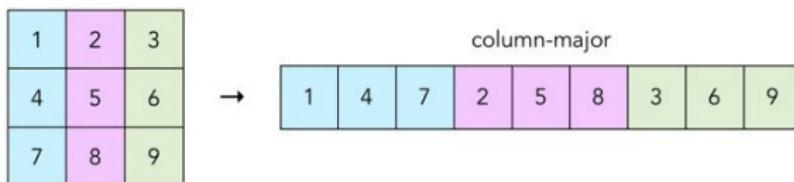

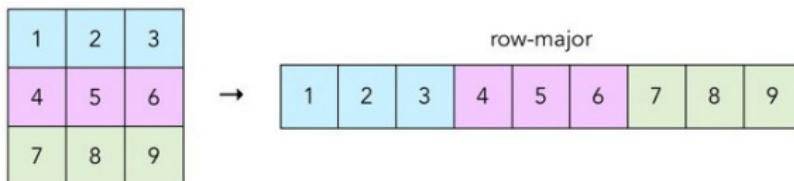

```
matrix_t mat;
matrix_init(&mat, rows, cols);

int elij = MGET(mat,i,j);
// elij = mat.data[ mat.cols*i + j ]

MSET(mat,i,j, 55);
// mat.data[ mat.cols*i + j ] = 55;
```

## Aside: Row-Major vs Col-Major Layout

- ▶ Many languages use **Row-Major** order for 2D arrays/lists
  - ▶ C, Java, Python, Ocaml,...
  - ▶  $\text{mat}[i]$  is a contiguous row,  $\text{mat}[i][j]$  is an element
- ▶ Numerically-oriented languages use **Column-Major** order
  - ▶ Fortran, Matlab/Octave, R, Ocaml (?)...
  - ▶  $\text{mat}[j]$  is a contiguous **column**,  $\text{mat}[i][j]$  is an element
- ▶ Being aware of language convention can increase efficiency

Source: The Craft of Coding

## Exercise: Matrix Summing

- ▶ How are the two codes below different?
- ▶ Are they doing the same number of operations?
- ▶ Which will run faster?

```
int sumR = 0;  
for(int i=0; i<rows; i++){  
    for(int j=0; j<cols; j++){  
        sumR += mat[i][j];  
    }  
}
```

```
int sumC = 0;  
for(int j=0; j<cols; j++){  
    for(int i=0; i<rows; i++){  
        sumC += mat[i][j];  
    }  
}
```

## Answer: Matrix Summing

- ▶ Show timing in `matrix_timing.c`
- ▶ `sumR` faster than `sumC`: caching effects
- ▶ Discuss timing functions used to determine duration of runs

```
> gcc -Og matrix_timing.c
```

```
> a.out 50000 10000
```

```
sumR: 1711656320 row-wise CPU time: 0.265 sec, Wall time: 0.265
```

```
sumC: 1711656320 col-wise CPU time: 1.307 sec, Wall time: 1.307
```

- ▶ `sumR` runs about 6 times faster than `sumC`
- ▶ Understanding why requires knowledge of the memory hierarchy and cache behavior

# Measuring Time in Code

- ▶ Measure CPU time with the standard `clock()` function; measure time difference and convert to seconds
- ▶ Measure Wall (real) time with `gettimeofday()` or related functions; fills struct with info on time of day (duh)

## CPU Time

```
#include <time.h>

clock_t begin, end;
begin = clock(); // current cpu moment

do_something();

end = clock(); // later moment

double cpu_time =
    ((double) (end-begin)) / CLOCKS_PER_SEC;
```

## Real (Wall) Time

```
#include <sys/time.h>

struct timeval tv1, tv2;
gettimeofday(&tv1, NULL); // early time

do_something();

gettimeofday(&tv2, NULL); // later time

double wall_time =
    ((tv2.tv_sec-tv1.tv_sec)) +
    ((tv2.tv_usec-tv1.tv_usec) / 1000000.0);
```

## Tools to Measure Performance: perf

- ▶ The Linux `perf` tool is useful to measure performance of an entire program
- ▶ Shows variety of statistics tracked by the kernel about things like memory performance
- ▶ **Examine** examples involving the `matrix_timing` program:  
`sumR` vs `sumC`
- ▶ **Determine** statistics that explain the performance gap between these two?

## Exercise: perf stats for sumR vs sumC, what's striking?

```
> perf stat $perfopts ./matrix_timing 8000 4000 row    ## RUN sumR ROW SUMMING
sumR: 1227611136 row-wise CPU time: 0.019 sec, Wall time: 0.019
Performance counter stats for './matrix_timing 8000 4000 row':          %SAMPLED
 135,161,407  cycles:u                                              (45.27%)
 417,889,646  instructions:u      # 3.09  insn per cycle          (56.22%)
  56,413,529  L1-dcache-loads:u                                         (55.96%)
   3,843,602  L1-dcache-load-misses:u # 6.81% of all L1-dcache hits (50.41%)
  28,153,429  L1-dcache-stores:u                                         (47.42%)
           125  L1-icache-load-misses:u                                     (44.77%)
  3,473,211  cache-references:u      # last level of cache        (56.22%)
  1,161,006  cache-misses:u       # 33.427 % of all cache refs (56.22%)

> perf stat $perfopts ./matrix_timing 8000 4000 col    # RUN sumC COLUMN SUMMING
sumC: 1227611136 col-wise CPU time: 0.086 sec, Wall time: 0.086
Performance counter stats for './matrix_timing 8000 4000 col':          %SAMPLED
 372,203,024  cycles:u                                              (40.60%)
 404,821,793  instructions:u      # 1.09  insn per cycle          (57.23%)
  61,990,626  L1-dcache-loads:u                                         (60.21%)
  39,281,370  L1-dcache-load-misses:u # 63.37% of all L1-dcache hits (45.66%)
  23,886,332  L1-dcache-stores:u                                         (43.24%)
           2,486  L1-icache-load-misses:u                                     (40.82%)
  32,582,656  cache-references:u      # last level of cache        (59.38%)
  1,894,514  cache-misses:u       # 5.814 % of all cache refs  (60.38%)
```

## Answers: perf stats for sumR vs sumC, what's striking?

### Observations

- ▶ Similar number of instructions between row/col versions
- ▶ #cycles lower for row version → higher insn per cycle
- ▶ **L1-dcache-misses:** marked difference between row/col version
- ▶ **Last Level Cache Refs :** many, many more in col version
- ▶ Col version: much time spent waiting for memory system to feed in data to the processor

### Notes

- ▶ The right-side percentages like (50.41%) indicate how much of how much of the time this feature is measured; some items can't be monitored all the time.
- ▶ Specific perf invocation is in  
`10-memory-systems-code/measure-cache.sh`

## Exercise: Time and Throughput

Consider the following simple loop to sum elements of an array from `stride_throughput.c`

```
int *data = ...; // global array
int sum_simple(int len, int stride){
    int sum = 0;
    for(int i=0; i<len; i+=stride)
    {
        sum += data[i];
    }
    return sum;
}
```

- ▶ Param `stride` controls step size through loop

- ▶ Interested in two features of the `sum_simple()` function:

1. Total Time to complete
2. **Throughput:**

$$\text{Throughput} = \frac{\#Additions}{\text{Second}}$$

- ▶ How would one **measure and calculate** these two in a program?
- ▶ As `stride` increases, **predict** how **Total Time** and **Throughput** change

# Answers: Time and Throughput

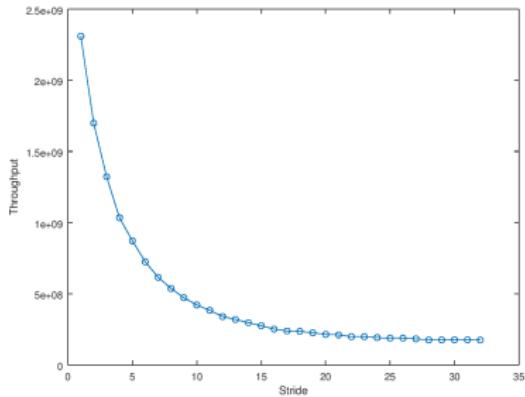

## Measuring Time/Throughput

Most interested in CPU time so

```
begin = clock();
sum_simple(length,stride);
end = clock();
cpu_time = ((double) (end-begin))
           / CLOCKS_PER_SEC;

throughput = ((double) length) /
             stride /
             cpu_time;
```

*Plot of Stride vs Throughput*

## Time vs Throughput

As stride increases...

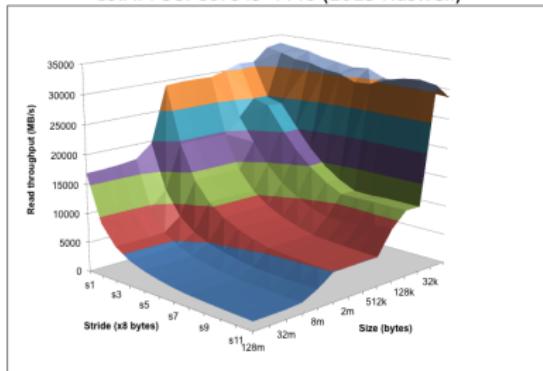

- ▶ Time decreases: doing fewer additions (duh)
- ▶ Throughput **decreases**

- ▶ Stride = 1: consecutive memory accesses
- ▶ Stride = 16: jumps through memory, more time

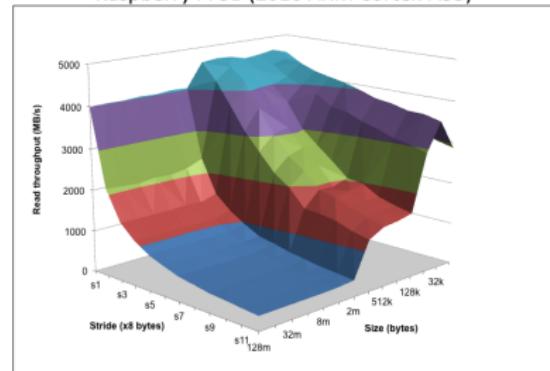

# Memory Mountains from Bryant/O'Hallaron

- ▶ Varying stride for a fixed length leads to decreasing performance, 2D plot
- ▶ Can also vary length for size of array to get a 3D plot
- ▶ Illustrates features of CPU/memory on a system
- ▶ The “Memory Mountain” on the cover of our textbook
- ▶ What **interesting structure** do you see?

CS:APP3e: Core i5-4440 (2013 Haswell)

Raspberry Pi 3B (2016 ARM Cortex-A53)

# Increasing Efficiency

- ▶ Can increase the efficiency of loop summing with tricks
- ▶ B/O'H use multiple *accumulators*: multiple variables for summing
- ▶ Facilitates pipelining / superscalar processor
- ▶ Code is significantly faster BUT much trickier and less readable
- ▶ May be compiler options which enable this but not with defaults in gcc -O3 (try searching [optimization options](#), ~67 pages)

```
// From Bryant/O'Hallaron
int sum_add4(int elems, int stride){
    int i,
        sx1 = stride*1, sx2 = stride*2,
        sx3 = stride*3, sx4 = stride*4,
        acc0 = 0, acc1 = 0,
        acc2 = 0, acc3 = 0;
    int length = elems;
    int limit = length - sx4;

    /* Combine 4 elements at a time */
    for (i = 0; i < limit; i += sx4) {
        acc0 = acc0 + data[i];
        acc1 = acc1 + data[i+sx1];
        acc2 = acc2 + data[i+sx2];
        acc3 = acc3 + data[i+sx3];
    }

    /* Finish any remaining elements */
    for (; i < length; i += stride) {
        acc0 = acc0 + data[i];
    }
    return acc0+acc1+acc2+acc3;
}
```

## Temporal and Spatial Locality

- ▶ In the beginning, there was only CPU and Memory
- ▶ Both ran at about the same speed (same clock frequency)
- ▶ CPUs were easier to make faster, began outpacing speed of memory
- ▶ Hardware folks noticed programmers often write loops like

```
for(int i=0; i<0; i++){  
    sum += array[i];  
}
```
- ▶ Led to development of faster memories exploit Locality
- ▶ **Temporal Locality:** memory recently used likely to be used again soon
- ▶ **Spatial Locality:** memory near to recently used memory likely to be used
- ▶ Register file and Cache were developed to exploit this: faster memory that is automatically managed

# The Memory Pyramid

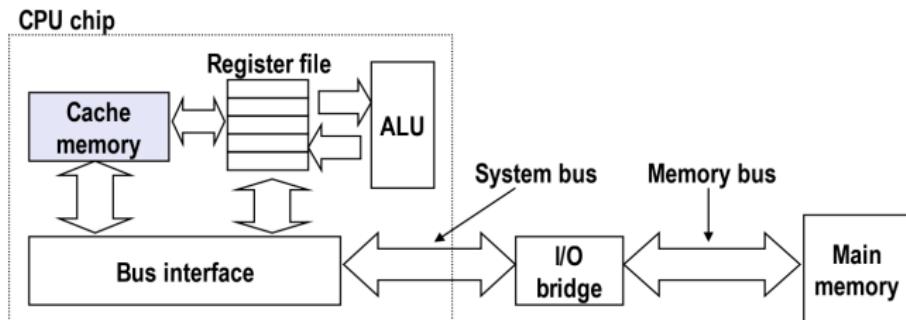

# Numbers Everyone Should Know

Edited Excerpt of [Jeff Dean's](#) talk on data centers.

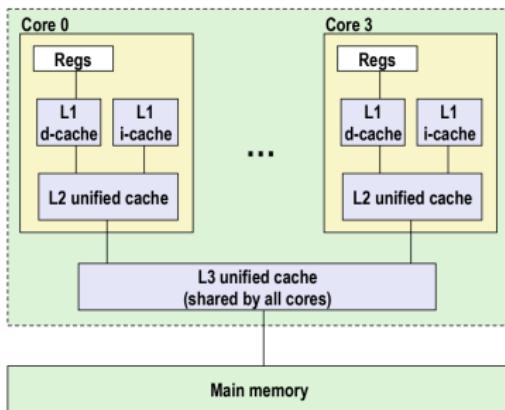

Reference	Time	Analogy
Register	-	Your brain
L1 cache reference	0.5 ns	Your desk
L2 cache reference	7 ns	Neighbor's Desk
Main memory reference	100 ns	This Room
Disk seek	10,000,000 ns	Salt Lake City

Big-O Analysis does NOT capture these; proficient programmers do

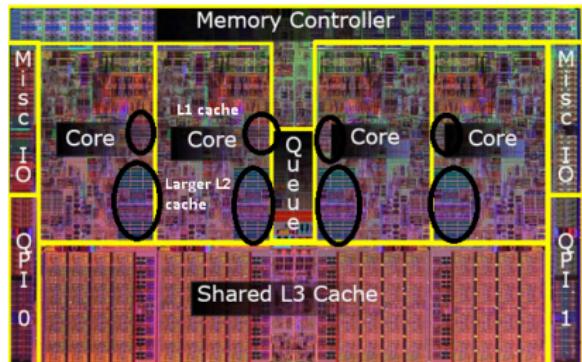

# Diagrams of Memory Interface and Cache Levels

Source: Bryant/O'Hallaron CS:APP 3rd Ed.

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Source: SO "Where exactly L1, L2 and L3 Caches located in computer?"

# Why isn't Everything Cache?

Metric	1985	1990	1995	2000	2005	2010	2015	2015/1985
SRAM \$/MB	2,900	320	256	100	75	60	25	116
SRAM access (ns)	150	35	15	3	2	1.5	1.3	115
DRAM \$/MB	880	100	30	1	0.1	0.06	0.02	44,000
DRAM access (ns)	200	100	70	60	50	40	20	10

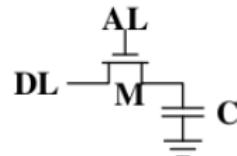

Figure 2.5: 1-T Dynamic RAM

"What Every Programmer Should Know About Memory" by Ulrich Drepper, Red Hat, Inc.

# Cache Principles: Hits and Misses

## CPU-Memory is a Client-Server

- ▶ CPU makes requests
- ▶ Memory system services request as fast as possible

## Cache Hit

- ▶ CPU requests memory at address 0xFFFF1234 be loaded into register %rax
- ▶ **Finds** valid data for 0xFFFF1234 in L1 Cache: **L1 Hit**
- ▶ Loads into register fast

## Cache Miss

- ▶ CPU requests memory at address 0xFFFF7890 be loaded into register %rax
- ▶ 0xFFFF7890 **not in L1**  
Cache: **L1 Miss**
- ▶ Search L2: if found move into L1, then %rax
- ▶ Search L3: if found move into L2, L1, %rax
- ▶ Search main memory: if found, move into caches, if not...

Wait, how could 0xFFFF7890 not be in main memory... ?

## Types of Cache Misses

### Compulsory “Cold” Miss: Program Getting Started

- ▶ All cache entries start with valid=0: cache contains leftover garbage from previous program runs
- ▶ After the cache “warms up” most entries will have Valid=1, data for running program

### Capacity Miss: Data Too Big to Fit

- ▶ **Working set** is set of memory being frequently accessed in a particular phase of a program run
- ▶ Large working set may exceed the size of a cache causing misses

### Conflict Miss: This Stall Occupied

- ▶ Internal **placement policy** of cache dictates where data goes
- ▶ If two needed piece of data both go to the same position in cache, leads to misses as they overwrite each other

# Memory Address Determines Location in a Cache

Cache is like a **Hash Table**

- ▶ Cache has a # of **Sets** which can hold a copy of Main Memory
- ▶ Each Main Memory address has some bits indicating
  - ▶ **Set** - where in cache data should go
  - ▶ **Tag** - identifier to track what's in cache
- ▶ Each cache Set can hold 1 or more **Lines** of data with a specific Tag
- ▶ Main Memory divides into cache **Blocks** which share Tag/Set and move in/out of cache together

*Address Bits to Cache Location*

- ▶ Bits from address determine location for memory in cache
- ▶ Direct-Mapped cache, 4 sets and 16 byte blocks/lines
- ▶ Load address 0x28

0 2 8  
0x28 = 00 10 1000  
| | |  
| | +--> Offset: 4 bits  
| +--> Set: 2 bits  
+--> Tag: Remaining bits

- ▶ 0x20 in the same line, will also be loaded int set #2

# Exercises: Anatomy of a Simple CPU Cache

MAIN MEMORY

	Addr	Addr Bits		Value
	00	00 00	0000	331
	08	00 00	1000	332
	10	00 01	0000	333
	18	00 01	1000	334
	20	00 10	0000	335
	28	00 10	1000	336
	30	00 11	0000	337
	38	00 11	1000	338
		...	.

	38	00 11	1000	338
		...	.	
	C0	11 00	0000	551
	C8	11 00	1000	552
	D0	11 01	0000	553
	D8	11 01	1000	554
	E0	11 10	0000	555
	E8	11 10	1000	556
	F0	11 11	0000	557
	F8	11 11	1000	558
		Tag Set Offset		

CACHE

				Blocks/Line
	Set	V	Tag	0-7    8-15
	00	1	*00	331    332
	01	1	00	333    334
	10	1	11	555    556
	11	1	*11	557    558
				0-7    8-15

## DIRECT-MAPPED Cache

- Direct-mapped: 1 line per set
- 16-byte lines = 4-bit offset
- 4 Sets = 2-bit index
- 8-bit Address = 2-bit tag
- Total Cache Size = 64 bytes  
4 sets \* 16 bytes

## HITS OR MISSES? Show effects

1. Load 0x08: MISS to set 00
2. Load 0xF0: MISS overwrite set 11
3. Load 0x18: HIT in set 01 no change

# Direct vs Associative Caches

## Direct Mapped

One line per set

Set	V	Tag	Blocks/Line	
			0-7	8-15
00	0	-	-	
01	1	00	333	334
10	1	11	555	556
11	1	00	337	338
			0-7	8-15

- ▶ Simple circuitry
- ▶ **Conflict misses** may result: 1 slot for many possible tags
- ▶ **Thrashing:** need memory with overlapping tags

vv  
0x10 = 00 01 0000 : in cache  
0xD8 = 11 01 1000 : conflict  
~~

## N-Way Associative Cache

Ex: 2-way = 2 lines per set

Set	V	Tag	Blocks	
			0-7	8-15
00	0	-	-	
	1	11	551	552
01	1	00	333	334
	1	11	553	554
10	1	11	555	556
	0	-	-	
11	1	00	337	338
	1	11	557	558
			0-7	8-15

- ▶ Complex circuitry → \$\$
- ▶ Requires an **eviction policy**, usually least recently used

# How big is your cache? Check Linux System special Files

## lscpu Utility

Handy Linux program that summarizes info on CPU(s)

```
> lscpu
Architecture: x86_64
CPU op-mode(s): 32-bit, 64-bit
Byte Order: Little Endian
Address sizes: 36 bits physical,
                48 bits virtual
CPU(s): 4
Vendor ID: GenuineIntel
CPU family: 6
Model: 58
Model name: Intel(R) Core(TM)
             i7-3667U CPU @ 2.00GHz
...
L1d cache: 64 KiB
L1i cache: 64 KiB
L2 cache: 512 KiB
L3 cache: 4 MiB
Vulnerability Meltdown: Mitigation; ...
Vulnerability Spectre v1: Mitigation ...
...
```

## Detailed Hardware Info

Files under /sys/devices/... show hardware info (caches)

```
> cd /sys/devices/system/cpu/cpu0/cache/
> ls
index0 index1 index2 index3 ...
> ls index0/
number_of_sets type level size
ways_of_associativity ...
> cd index0
> cat level type number_* ways_* size
1 Data 64 8 32K
> cd ../index1
> cat level type number_* ways_* size
1 Instruction 64 8 32K
> cd ../index3
> cat level type number_* ways_* size
3 Unified 8192 20 10240K
```

## Disks: Persistent Block Storage

- ▶ Have discussed a variety of fast memories which are **small**
- ▶ At the bottom of the pyramid are **disks**: slow but **large** memories
- ▶ These are **persistent**: when powered off, they retain information

## Using Disk as Main Memory

- ▶ Operating Systems can create the illusion that main memory is larger than it is in reality
- ▶ Ex: 2 GB DRAM + 6 GB of disk space = 8 GB Main Memory
- ▶ Disk file is called **swap** or a **swap file**
- ▶ Naturally much slower than RAM so OS will try to limit its use
- ▶ A **Virtual Memory** system manages RAM/Disk as main memory, will discuss later in the course

## Flavors of Permanent Storage

- ▶ Permanent storage often referred to as a “drive”
- ▶ Comes in many variants but these 3 are worth knowing about in the modern era
  1. Rotating Disk Drive
  2. Solid State Drive
  3. Magnetic Tape Drive
- ▶ Surveyed in the slides that follow

# Ye Olde Rotating Disk

- ▶ Store bits “permanently” as magnetized areas on special platters
- ▶ Magnetic disks: moving parts → slow
- ▶ Cheap per GB of space

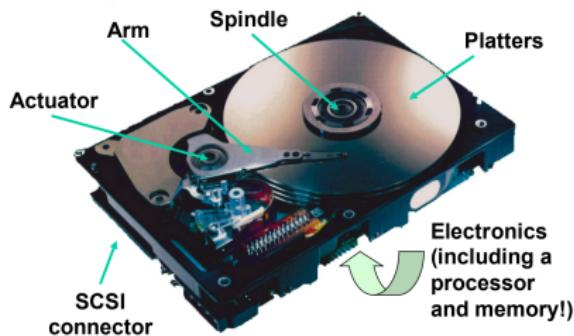

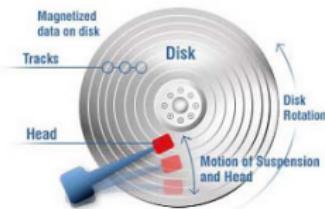

Image courtesy of Seagate Technology

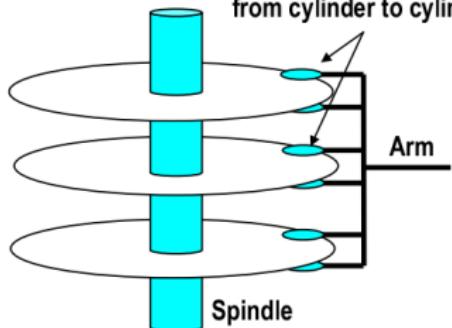

Source: CS:APP Slides

HARD DRIVE DATA READ & WRITE OPERATION MOTION DIAGRAM

Read/write heads move in unison from cylinder to cylinder

# Rotating Disk Drive Features of Interest

## Measures of Quality

- ▶ Capacity: bigger is usually better
- ▶ Seek Time: delay before a head assembly reaches an arbitrary track of the disk that contains data
- ▶ Rotational Latency: time for disk to spin around to correct position; faster rotation → lower Latency
- ▶ Transfer Rate: once correct read/write position is found, how fast data moves between disk and RAM

## Sequential vs Random Access

Due to the rotational nature of Magnetic Disks...

- ▶ Sequential reads/writes comparatively FAST
- ▶ Random reads/writes comparatively very SLOW

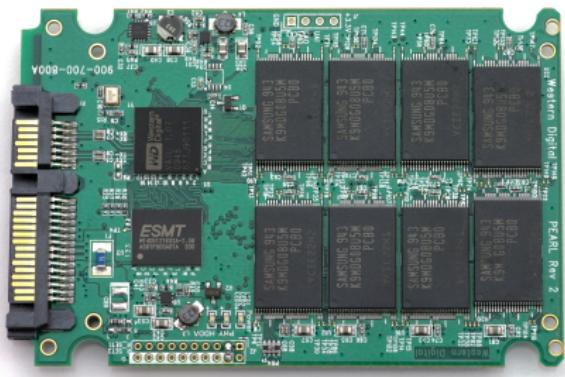

# Solid State Drives

- ▶ No moving parts → speed
- ▶ Most use “flash” memory, non-volatile circuitry
- ▶ Major drawback: limited number of **writes**, disk wears out eventually
- ▶ Reads faster than writes
- ▶ Sequential somewhat faster than random access
- ▶ **Expensive:**

*A 1TB internal 2.5-inch hard drive costs between \$40 and \$50, but as of this writing, an SSD of the same capacity and form factor starts at \$250. That translates into*

- 4 to 5 cents/GB for HDD
- 25 cents/GB for the SSD.

*PC Magazine, “SSD vs HDD” by Tom Brant and Joel Santo Domingo March 26, 2018*

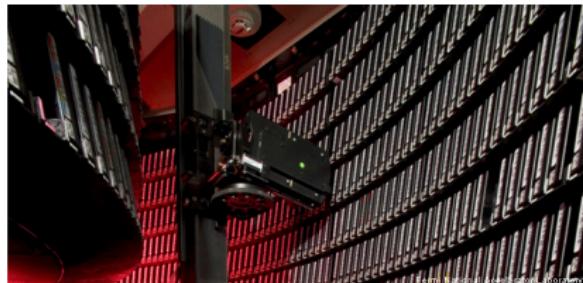

# Tape Drives

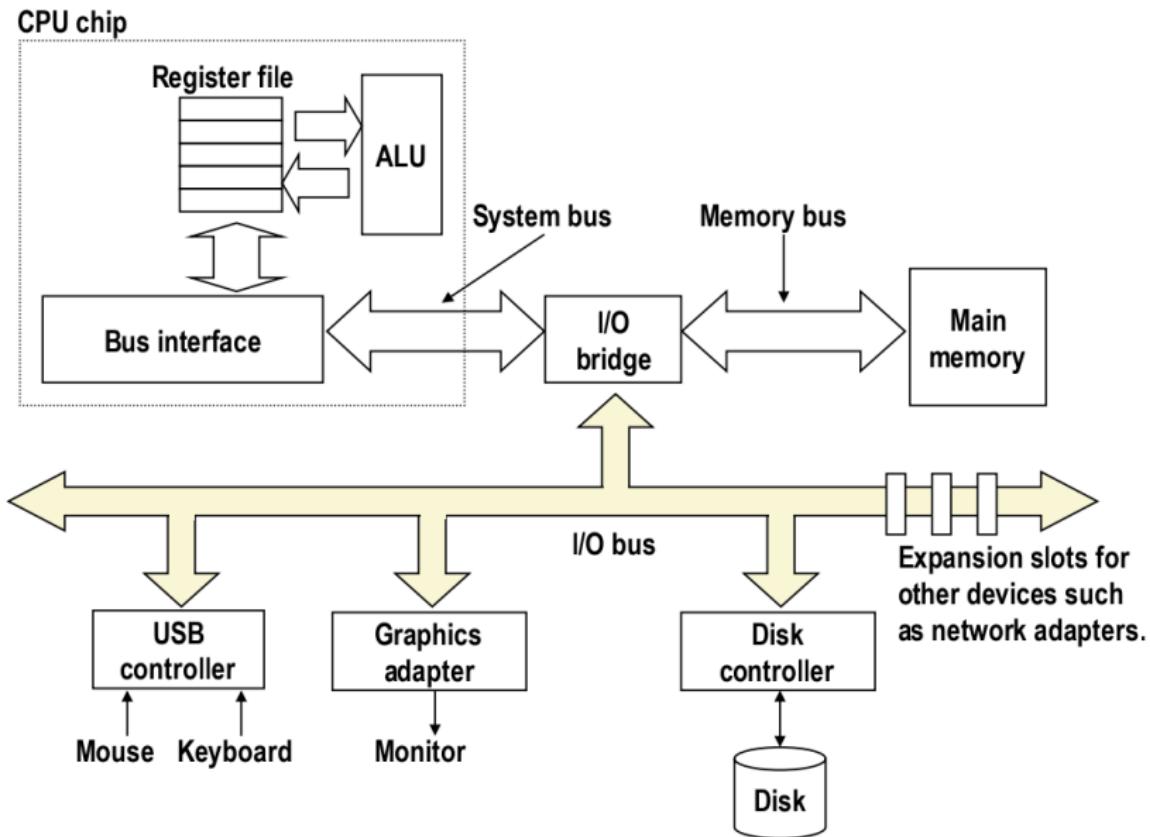

- ▶ Slowest yet: store bits as magnetic field on a piece of “tape” a la 1980’s cassette tape / video recorder

- ▶ Extremely cheap per GB so mostly used in backup systems
- ▶ Ex: CSELabs does nightly backups of home directories, recoverable from tape at request to Operator

# The I/O System Connects CPU and Peripherals

# Terminology

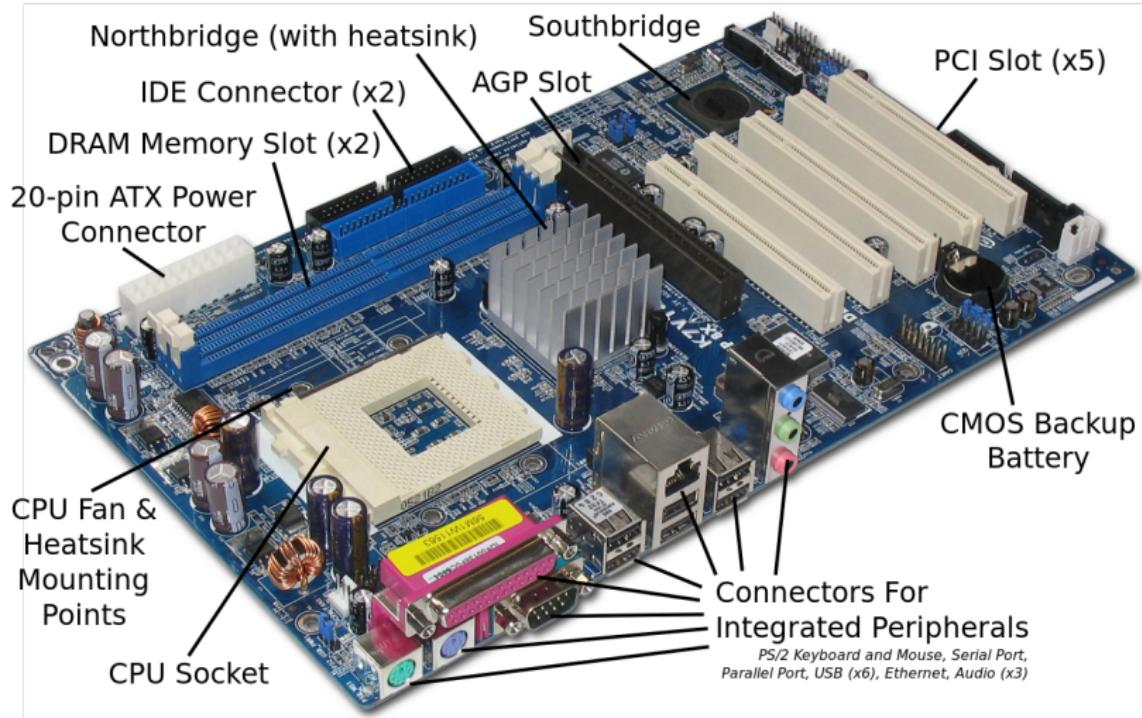

**Bus** A collection of wires which allow communication between parts of the computer. May be serial (single wire) or parallel (several wires), must have a communication protocol over it.

**Bus Speed** Frequency of the clock signal on a particular bus, usually different between components/buses requiring interface chips  
CPU Frequency > Memory Bus > I/O Bus

**Interface/Bridge** Computing chips that manage communications across the bus possibly routing signals to correct part of the computer and adapting to differing speeds of components

**Motherboard** A printed circuit board connects to connect CPU to RAM chips and peripherals. Has buses present on it to allow communication between parts. *Form factor* dictates which components can be handled.

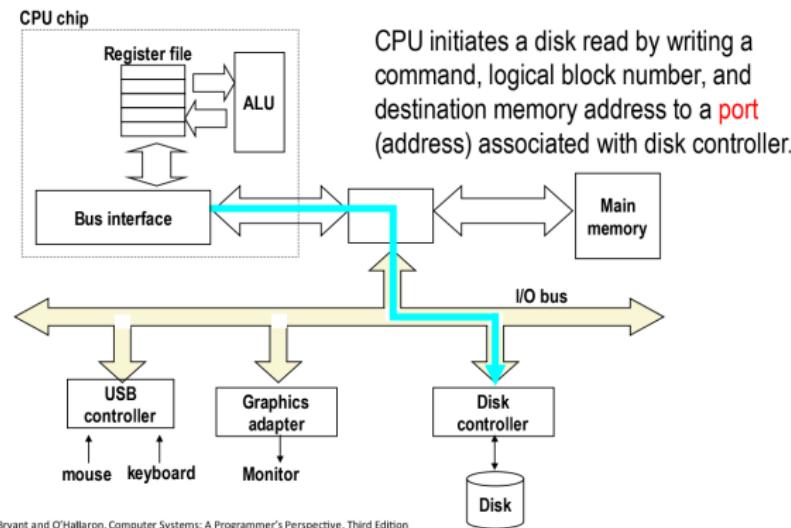

# The Motherboard

Source: Wikipedia

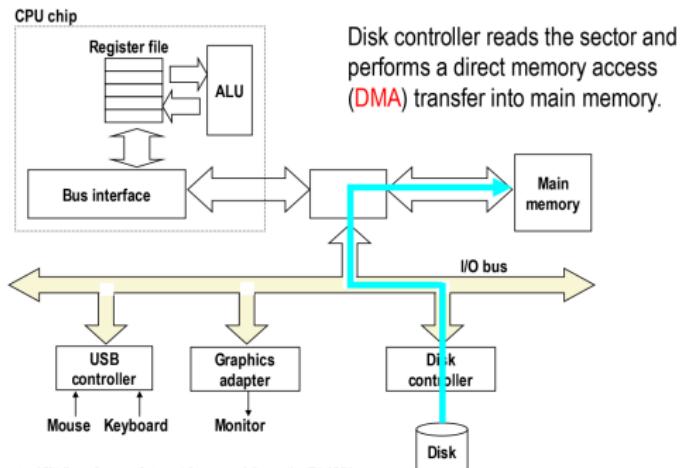

# Memory Mapped I/O

- ▶ Modern systems are a collection of devices and microprocessors
- ▶ CPU usually uses **memory mapped I/O**: read/write certain memory addresses translated to communication with devices on I/O bus

# Direct Memory Access

- ▶ Communication received by *other* microprocessors like a Disk Controller or Memory Management Unit (MMU)
- ▶ Other controllers may talk: Disk Controller loads data directly into Main Memory via **direct memory access**

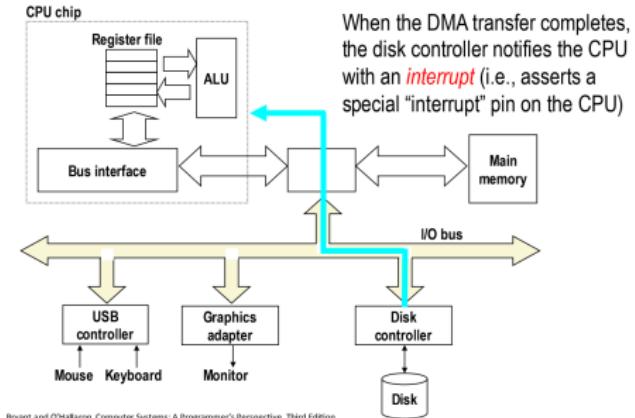

# Interrupts and I/O

Recall access times

Place	Time
L1 cache	0.5 ns
RAM	100 ns
Disk	10,000,000 ns

- ▶ While running Program X, CPU reads an int from disk into %rax
- ▶ Communicates to disk controller to read from file
- ▶ Rather than wait, OS puts Program X to “sleep”, starts running program Y

- ▶ When disk controller completes read, signals the CPU via an **interrupt**, electrical signals indicating an event
- ▶ OS handles interrupt, schedules Program X as “ready to run”

## Interrupts from Outside and Inside

- ▶ Examples of events that generate interrupts
  - ▶ Integer divide by 0
  - ▶ I/O Operation complete
  - ▶ Memory address not in RAM (Page Fault)
  - ▶ User generated: x86 instruction int 80
- ▶ Interrupts are mainly the business of the Operating System
- ▶ Usually cause generating program to immediately transfer control to the OS for handling
- ▶ When building your own OS, must write “interrupt handlers” to deal with above situations
  - ▶ Divide by 0: **signal** program usually terminating it
  - ▶ I/O Complete: schedule requesting program to run
  - ▶ Page Fault: sleep program until page loaded
  - ▶ User generated: perform system call
- ▶ User-level programs will sometimes get a little access to interrupts via **signals**, a topic for CSCI 4061
