Logistics

Reading: Grama Ch 2

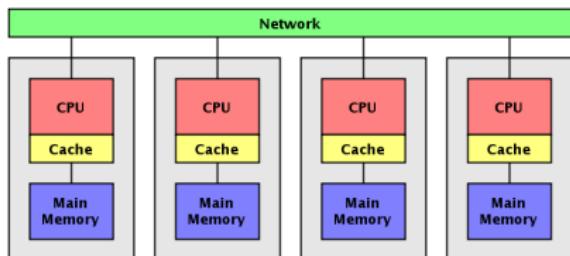

- ▶ **Focus on 2.3-5**, material pertaining to **distributed memory**
 - ▶ We will return to shared memory arch later in the course
 - ▶ Cache Coherence, PRAM models, False Sharing, Memory Bus are all shared memory topics we'll discuss later
- ▶ Sections 2.1 and 2.2 optional, deeper architectures
- ▶ Sections 2.6 and 2.7 encouraged, deeper on networks

SISD, SIMD, MIMD, SPAM, and other 4-letter words

- ▶ Traditional CPU, Single Instruction Single Data (SISD)
ADD r1, r2 # add int in r2 to r1
- ▶ Most computers now have cpu instructions to add multiple
PHADD mm1, mm2 # add two ints in mm2 to ints in mm1
- ▶ Smart compilers will select **SIMD / Vector instructions** when appropriate architecture support is available
- ▶ Explicit hardware parallelism is good for multimedia stuff (graphics, games, images, sound, videos)
- ▶ Flynn's taxonomy of Parallel Architecture includes
 - I: Instruction SISD SIMD SPMD P: Program
 - D: Data MISD MIMD MPMD
- ▶ Some parallel programs exist as Multiple Program Multiple Data (MPMD) like client server models (`client.c` and `server.c` are separate programs)
- ▶ Our focus and the most common type of parallel program:
Single Program Multiple Data (SPMD): *Write one program which processes different hunks of data in parallel*

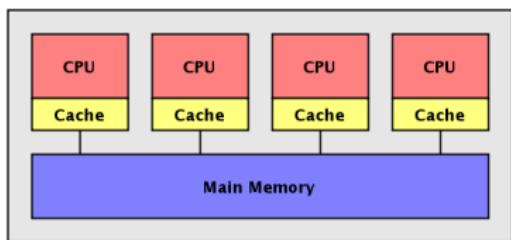

Distributed vs Shared Memory Architectures

Distributed Memory

Source: Kaminsky/Parallel Java

Shared Memory

Source: Kaminsky/Parallel Java

- ▶ Far more scalable/cost effective
- ▶ Sharing information requires explicit send/receive commands between processors
- ▶ Communication requires more care/more expensive

- ▶ Convenience: no explicit send/receive, write shared memory address
- ▶ Requires coordination to prevent corrupting memory
- ▶ Communication cost is low but requires discipline

Modeling Distributed Memory Parallel Computers

Will spend a some time discussing networks used in parallel computing. These have consequences for algorithms, but unless you're building your own machine (min cost \$1M) you're stuck with what you get. Examples:

1. You can test programs on your laptop which likely has 4 cores and no interconnect; MPI models distributed memory as individual processes but scale is limited...
2. We will use the Zaratan cluster for MPI programming which uses an [Infiniband Interconnect](#) comprised of switches / processors / storage in a [Switched Fabric Topology](#), balances cost and scale reasonably
3. If you have a chance to work on the [#7 Super Computer in the World, Fugaku, in Japan](#), it is reported to have a [Multi-dimensional Torus Topology](#) dubbed "Tofu"

Communication protocols on individual machines vary in details BUT coding via a library like MPI will utilize the best available underlying tech possible

Static Networks for Distributed Machines

- ▶ String up a bunch of **Processing Elements (PEs)**
- ▶ Decide which PE is connected to which other PE
- ▶ Live with the effects on cost of communication

Communication Cost Factors

When sending a message of size m words of memory

- ▶ t_s : Startup time, incurred once
- ▶ t_h : Per-hop time, overhead incurred for each link between source and destination
- ▶ t_w : Per-word transfer time between two nodes, takes $t_w \times M$ time for each link between source and destination
- ▶ L : number of links to traverse
- ▶ M : number of words being sent
- ▶ Typical model for communication time w/ packet routing

$$t_{comm} = t_s + L t_h + M t_w \text{ (Cut-Through Routing)}$$

Basics of Network Design : Cost vs Communication

- ▶ Balance number of links / connection pattern complexity
- ▶ VS “Distance” between PEs + Contention

(a)

(b)

Figure 2.14 (a) A completely-connected network of eight nodes; (b) a star connected network of nine nodes.

(a)

(b)

Figure 2.15 Linear arrays: (a) with no wraparound links; (b) with wraparound link.

Grid and Torus

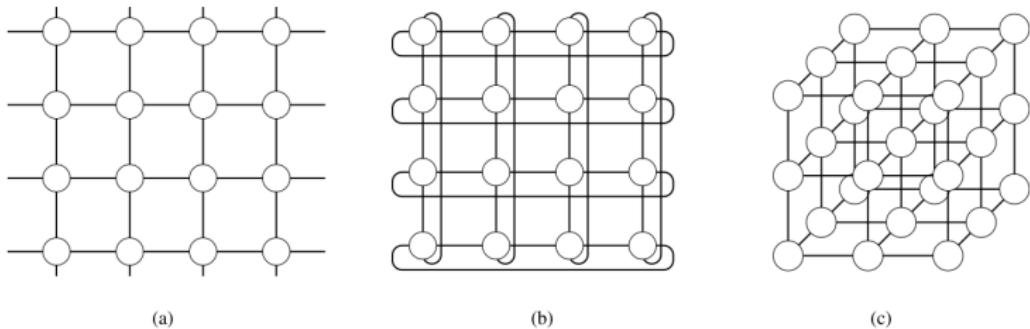

Figure 2.16 Two and three dimensional meshes: (a) 2-D mesh with no wraparound; (b) 2-D mesh with wraparound link (2-D torus); and (c) a 3-D mesh with no wraparound.

Source: Grama, Sec 2.4.3

- ▶ Common arrangement of links between PEs
- ▶ Each PE node connected to neighbors
- ▶ When wrapping around, grid becomes a torus
- ▶ For a 2D torus with p nodes, **how many links are required?**
- ▶ *Hint: surprisingly simple, think of each processor “owning” down and right links*
- ▶ **How many links in a 3D torus?**

Exercise: HyperCube

- ▶ D-dimension hypercube: connect two $(D - 1)$ dimension hypercubes, link corresponding nodes
- ▶ How many nodes and links in a D-dimension hypercube?
- ▶ Hint: Nodes are easy, links are tricky, try Grama textbook...

Answers: HyperCube

D-dimensional Hypercube has

- ▶ 2^D Processors
- ▶ $2^D \times D/2$ links

Can show this via Proof by Induction but that's not our focus

That's a lot of Links

- ▶ Many communication patterns have excellent performance on a hypercube
- ▶ Building one requires wiring processors together in a highly complex manner¹
- ▶ Ex: 10-dimensional hypercube with 1024 Processors each with 10 links to a unique set of other processors
- ▶ Hypercubes are a favorite theoretical topology and useful in some cases for algorithm analyses but ...
- ▶ Too expensive/complex for large-scale machines

¹Academic papers that describe new network architectures sometimes include *wiring algorithms* to show their complex network is actually practical to construct in reality: [example](#)

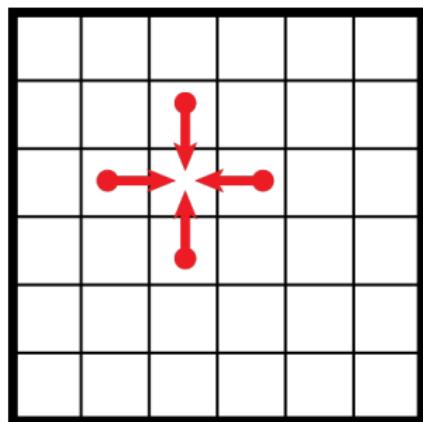

Exercise: Compare Networks on Parallel Stencil

- ▶ P processors
- ▶ Network 1: 2D-Mesh: around $2P$ links
- ▶ Network 2: $\log_2(P)$ dim. Hypercube w/ $(P \log_2(P)/2)$ links
- ▶ **Discuss** advantages/disadvantages of Mesh vs Hypercube arrangement for this application
- ▶ Outline an algorithm, estimate cost-effectiveness of code+hardware

Image “blurring”

- ▶ A large image is distributed across the P processors
- ▶ Each proc holds a 2D hunk of the image
- ▶ To blur the entire image, must assign RGB values which are average of “neighborhood”

Stencil

Answers: Compare Networks on Parallel Stencil

- ▶ Divide image into 2D hunks
- ▶ PEs must communicate with other PEs that have neighboring hunks of the image

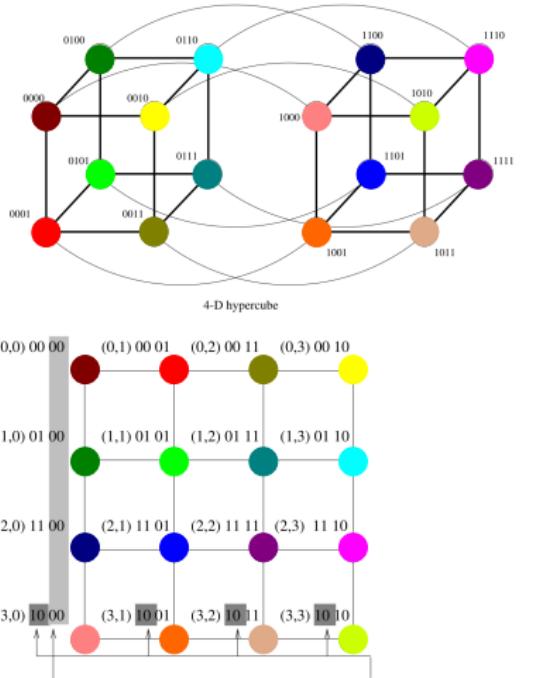

2D Mesh

- ▶ Maps VERY easily onto a 2D Mesh / Grid / Torus
- ▶ PEs locally blur own portion of image
- ▶ Exchange boundary pixels with 4 neighbors except for outer edge PEs

Answers: Compare Networks on Parallel Stencil

Hypercube

- ▶ Intuition: have many more links than in the 2D Torus, should be possible to place neighboring pixel hunks on neighboring procs
- ▶ *Embed 2D-Mesh into a Hypercube:* discussed in Grama 2.7.1, uses Gray Codes for Proc Numbering and is beyond in-class / exam questions (perhaps an assignment problem)
- ▶ After embedding Mesh in Hypercub, use Mesh algorithm

Processors in a column have identical two least-significant bits

Processors in a row have identical two most-significant bits

Network Embedding

- ▶ Some algorithms work well in a particular network
- ▶ When running them on another network, look for an **embedding** that replicates (as much as possible) features of the original network
- ▶ Embedding (informally):
 - ▶ Assignment of PEs in network A to PEs in network B
 - ▶ Assignment of links network A to links in network B
- ▶ Assignments lead to consequences
 - ▶ Ex: PE4 and PE5 are connected by a single link in Network A but are 2 links apart in Network B
 - ▶ Ex: In network A, parts of links X,Y,Z are all mapped onto Link W in network B
- ▶ Metrics like **Dilation** and **Congestion** evaluate the quality of different embedding choices
- ▶ Previous example found it is possible embed 2D Mesh in a Hypercube with Dilation / Congestion of 1

Exercise: Compare Networks on Parallel Sum

- ▶ P processors (assume P is a power of 2)
- ▶ Network 1: 2D-torus: $2P$ links
- ▶ Network 2: $\log_2(P)$ dim. Hypercube w/ $(P \log_2(P)/2)$ links
- ▶ **Discuss** advantages/disadvantages of torus vs hypercube arrangement for this application
- ▶ Outline an algorithm, estimate cost-effectiveness of code+hardware

Sum Array of Numbers

- ▶ Each proc holds a hunk of the data array
- ▶ Want total sum on root PE0 at end of algorithm
- ▶ **State your algorithm:** Try to minimize communication at each step, exploit as much parallelism as possible

Networks

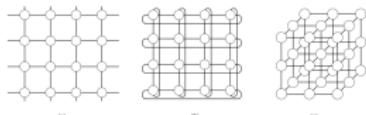

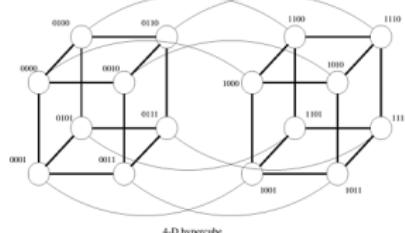

Figure 2.16 Two and three dimensional meshes: (a) 2-D mesh with no wraparound; (b) 2-D mesh with wraparound link (2-D torus); and (c) a 3-D mesh with no wraparound.

Answers: Compare Networks: Parallel Sum

Goal: Get sum on Proc 0

First, each Proc sums its own chunk of numbers then...

2D Torus: N by N Square

- ▶ Send values UP rows then LEFT across columns
 - ▶ $2 \times N$ Communication steps, always neighbors
 - ▶ Many Procs **Idle** during communication
- ▶ Other Communication steps will result in multi-hop communication with non-neighbor procs - will revisit this later

N-dimensional HyperCube

- ▶ Each Proc has a binary address: ex: 100110
- ▶ Starting with bit $i = (N - 1)$ while $i > 0$
 - ▶ Each Proc with bit $i == 1$ sends to $i == 0$
 - ▶ Decrement i , repeat
- ▶ Takes N communication steps

Communication Patterns Later

- ▶ We will talk more about Parallel Sum later
- ▶ Parallel Sum is an example of a **reduction** - general communication pattern that recurs often in Parallel Computing
- ▶ Covered in more detail in Section 6.6
- ▶ Parallel Sum is discussed in [Lecture notes by Susan Hayes](#)

Characteristics of Various Networks

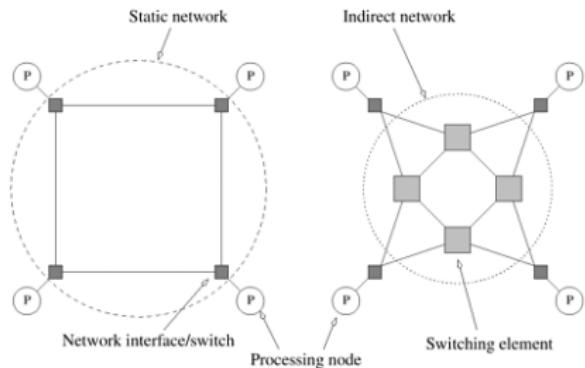

Table 2.1 A summary of the characteristics of various static network topologies connecting p nodes.

Network	Diameter	Bisection Width	Arc Connectivity	Cost (No. of links)
Completely-connected	1	$p^2/4$	$p - 1$	$p(p - 1)/2$
Star	2	1	1	$p - 1$
Complete binary tree	$2 \log((p + 1)/2)$	1	1	$p - 1$
Linear array	$p - 1$	1	1	$p - 1$
2-D mesh, no wraparound	$2(\sqrt{p} - 1)$	\sqrt{p}	2	$2(p - \sqrt{p})$
2-D wraparound mesh	$2\lfloor\sqrt{p}/2\rfloor$	$2\sqrt{p}$	4	$2p$
Hypercube	$\log p$	$p/2$	$\log p$	$(p \log p)/2$
Wraparound k -ary d -cube	$d\lfloor k/2 \rfloor$	$2k^{d-1}$	$2d$	dp

Several metrics described in textbook

- ▶ *Diameter*: max hops away any two procs can be
- ▶ *Bisection width*: remove N links to get 2 networks, equal size
- ▶ *Arc Connectivity*: remove N links to get 2 networks, any size
- ▶ *Cost*: can correspond to number of links

Dynamic Networks

- ▶ In a static network, connections are fixed
- ▶ Dynamic networks use switches: send data into network with destination, may alter a connection to point in a different direction
- ▶ Akin to the internet: packet switching network
- ▶ **Most modern HPC networks are Dynamic:** balances cost and scale better than the older static networks

Fat Trees

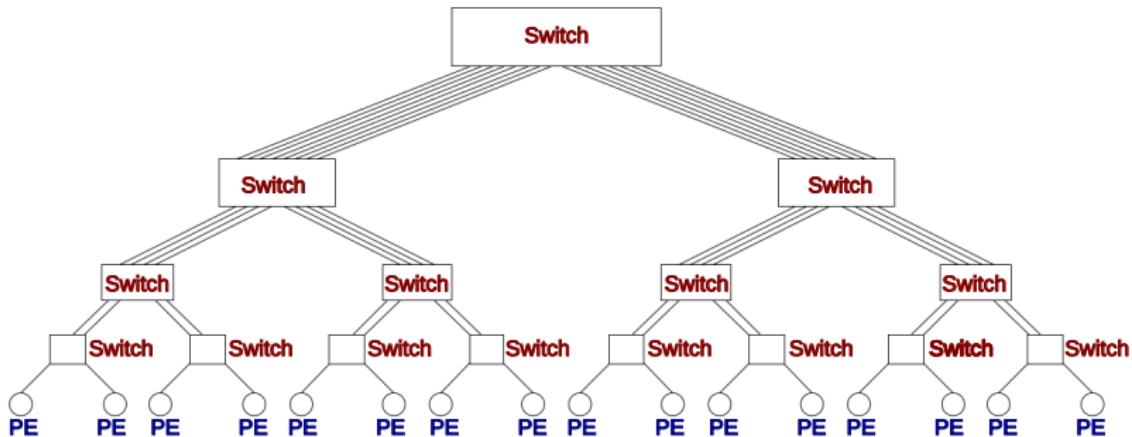

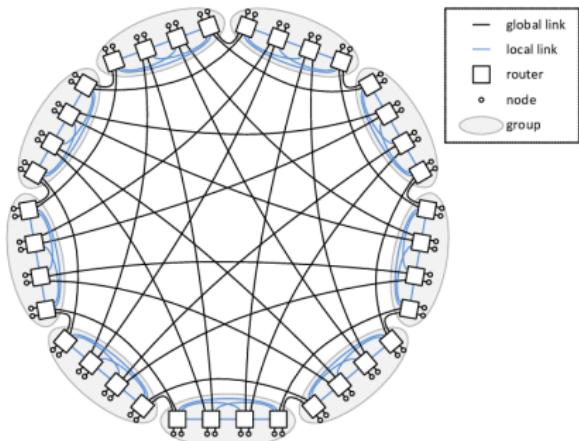

Figure 2.19 A fat tree network of 16 processing nodes.

Often used as network switches are inexpensive and widely available while still providing good communication speeds

Dragonfly Networks

Source: [Garcia et al. International Conference on Parallel Processing 2012](#)

- ▶ Some years ago a new HPC network topology coined “Dragonfly Networks” were introduced
- ▶ Proved influential due to...
- ▶ Low diameter: limits number of hops between any nodes (processors)
- ▶ “Groups” are fully interconnected
- ▶ Low Cost due to use of available commodity switches

Topology vs Interconnect

- ▶ The “shapes” we’ve seen so far are examples of network **Topology** which dictates how networks are interconnected, how many links required, diameter of the network, etc.
- ▶ The specific hardware used to create the network is not part of the description
- ▶ Most HPC facilities will describe the **Interconnect** they use: specific technology for communication
- ▶ Two most common Interconnects in Top-500 HPC facilities
 - ▶ **Infiniband**: Various owners/vendors (recently NVidia)
 - ▶ **Slingshot-11**: Cray (Hewlett Packard Enterprises)
- ▶ Interconnects usually support configuration into various Topologies: Slingshot-11 can be in Dragonfly, Fat-Tree, Butterfly, etc. according to docs

Routing: Store/Forward Packet and Packet Switching

When sending messages, intermediate nodes must decide what to do with a message: **Routing protocol/scheme**

Store and Forward

- ▶ Accumulate the whole message (all M words), store it until it can be forwarded to next hop
- ▶ Easy to build but requires large-ish internal buffers and generally has bad performance

Standard Packet Switching

- ▶ Break message into chunks (packets)
- ▶ Use packet header to carry error-correction info, routing info
- ▶ Optimized for the unreliable internet: go around overloaded / dead nodes, adjust to faster paths if found
- ▶ Better but incurs robustness overhead isn't necessary present in most reliable HPC machine networks

Routing: Cut-Through Communications

- ▶ Standard in HPC network design to optimize communication protocol: sacrifice some robustness to improve speed
- ▶ Cut-through Routing is an abstract version of this
- ▶ Similar to packet switching: break message into chunks
- ▶ Send a *tracer* from source to destination to determine route - all packets then follow that route
- ▶ Send message in *flits* (packets) along tracer route - reduces latency over Store/Forward
- ▶ Minimize data in packet for error correction, re-routing, etc. - reduced overhead vs Standard Packet Switching
- ▶ Comm time dominated by initial path determination $t_h L$ and total message size $t_w M$

Our Approach

Algorithm + Specific Network

Assume Cut-Through Routing,
account for hops between PEs

$$t_{comm} = t_s + L t_h + t_w M$$

- ▶ Simplified model for Comm but reasonable enough to guide algorithm decisions on how to utilize specific network
- ▶ Minimize L between communicating PEs in algorithms
- ▶ L changes with topology: e.g. Hypercube needs fewer communication steps than a Torus due to more abundant links

Algorithm + Arbitrary Network

Will ignore network topology,
congestion, number of hops

$$t_{comm} = t_s + t_w M$$

- ▶ Abstracted away from specific network features which will vary
- ▶ Ignores path lengths, unrealistic but understandable when network structure is unknown
- ▶ Still accounts for number and size of communications in algorithm
