

# CMSC216: C Basics

Chris Kauffman

*Last Updated:*  
*Thu Feb 12 10:36:14 AM EST 2026*

# CMSC216 Logistics

## Reading

- ▶ C references (any / all), whole language:  
types, pointers, addresses, arrays, conditionals, loops, structs, strings,  
malloc/free, preprocessor, compilation etc.
- ▶ C References are any of...
  - ▶ “The C Programming Language” book by Kernighan / Ritchie
  - ▶ Free refs linked at bottom of ELMS/Canvas Frontpage

## Assignments

- ▶ Lab03 due Sun
- ▶ P1 Due Mon
- ▶ Exam 1 Next Week

*Past students to Present concerning Project 1:  
Start EARLY, end Happy (or at least less stressed)*

## Goals

Wrap up overview of basic C / machine semantics

## Announcements

### Project 1 Due Date Imminent

- ▶ If you've not started P1, you'll likely need to submit late
- ▶ Expect it to take longer than you think: most past students report as much
- ▶ Time allotted in Mon Discussion to help students wrap up

### Exam 1 in 1 Week

- ▶ Open Resource Exam Rules are now posted
- ▶ Will release some practice exam material over the weekend
- ▶ Monday discussion will provide time to take simulate exam circumstances - attend to practice

# Every Programming Language

Look for the following as it should almost always be there

- Comments
- Statements/Expressions
- Variable Types
- Assignment
- Basic Input/Output (`printf()` and `scanf()` from HW1)
- Function Declarations
- Conditionals (if-else)
- Iteration (loops)
- Aggregate data (arrays, structs, objects, etc)
- Library System

## Exercise: Traditional C Data Types

These are the traditional data types in C

Bytes*	Name	Range
INTEGRAL		
1	char	-128 to 127
2	short	-32,768 to 32,767
4	int	-2,147,483,648 to 2,147,483,647
8	long	-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
FLOATING		
4	float	$\pm 3.40282347E\pm 38$ (6-7 significant decimal digits)
8	double	$\pm 1.79769313486231570E\pm 308$ (15 significant decimal digits)
POINTER		
4/8	pointer	Pointer to another memory location, 32 or 64bit <code>double *d or int **ip or char *s or void *p (!?)</code>
	array	Pointer to a fixed location <code>double [] or int [] [] or char []</code>

\*Number of bytes for each type is NOT standard but sizes shown are common.  
Portable code should NOT assume any particular size which is a huge pain in the @\$\$.

Inspect types closely and discuss the following:

1. Ranges of integral types?
2. Missing types you expected?
3. void what now?
4. How do you say char?

## Answers: Traditional C Data Types

### Ranges of **signed integral types**

Asymmetric: slightly more negative than positive

char is -128 to 127

Due to use of **Two's Complement** representation, many details and alternatives later in the course.

### Missing: Boolean

Every piece of data in C is either truthy or falsey:

```
int x; scanf("%d", &x);
if(x){ printf("Truthy"); } // very common
else { printf("Falsey"); }
```

Typically 0 is the only thing that is falsey

### Missing: String

- ▶ char holds a single character like 'A' or '5'
- ▶ No String type: arrays of char like char str[] or char \*s
- ▶ char pronounced **CAR / CARE** like "character" (debatable)

## Recall: Pointers, Addresses, Dereferences

type *ptr;	<b>Declares</b> a pointer variable
type* ptr;	<b>Declares</b> a pointer variable <sup>1</sup>
*ptr = val;	<b>Dereferences</b> pointer to set value pointed at
other = *ptr;	<b>Dereferences</b> pointer to get value pointed at

```
1 int *iptr;                      // Declare a pointer
2 int x = 7;                      // Declare/set an int
3 iptr = &x;                      // Set pointer
4 int y = *iptr;                  // Deref-ptr, gets x
5 *iptr = 9;                      // Deref-set ptr, changes x
6
7 double z = 1.23;                // Declare/set double
8 double *dptr = &z;              // Declare/set double ptr
9 *dptr = 4.56;                  // Deref-set ptr, changes z
10
11 printf("x: %d z: %f\n",      // print via derefs
12     *iptr, *dptr);
```

Declaring pointer variables to specific types is the *normal and safest* way to write C code but can be circumvented

---

<sup>1</sup>While `int *p;` and `int* p;` do the same thing, placing the `*` next to the variable name is the more common style in C for cases like `int a, *p, b;`

## Normal Pointers are Typed

Compiler enforces that `int*` pointers point at integers and nothing else. Code violating this will generate **Compiler-Time Errors** in the general category of a **Type Error**

```
1 // pointer_type_error.c: compiler will detect and
2 // error when assigning a pointer to refer to the
3 // wrong type of data. This code has an
4 // intentional error and WILL NOT COMPILE.
5
6 #include <stdio.h>
7 int main(){
8     int a = 10;
9     int *aptr = &a;      // int pointer to int
10    double b = 4.56;
11    double *bptr = &b; // double pointer to double
12    aptr = &b;          // ERROR: int pointer to double
13    printf("*aptr is %d\n",*aptr);
14    return 0;
15 }
16 // >> gcc pointer_type_error.c
17 // pointer_type_error.c: In function main:
18 // pointer_type_error.c:12:8:: error: assignment to
19 // int * from incompatible pointer type double *
20 // [-Wincompatible-pointer-types]
```

## Exercise: Legacy of the Void (Pointer)

```
void *ptr; // void pointer
```

- ▶ Declares a pointer to something/anything
- ▶ Useful to store an arbitrary memory address
- ▶ Removes compiler's ability to **Type Check** so introduces risks managed by the programmer

### Example: void\_pointer.c

- ▶ Predict output
- ▶ What looks screwy?

```
1 // void_pointer.c: pluses and perils
2 #include <stdio.h>
3 int main(){
4     int a = 5;
5     double x = 1.2345;
6     void *ptr;
7
8     ptr = &a;
9     int b = *((int *) ptr);
10    printf("%d\n",b);
11
12    ptr = &x;
13    double y = *((double *) ptr);
14    printf("%f\n",y);
15
16    int c = *((int *) ptr);
17    printf("%d\n",c);
18
19    return 0;
20 }
```

# Answers: Legacy of the Void (Pointer)

```
>> cat -n void_pointer.c
 1 // Demonstrate void pointer dereferencing and the associated
 2 // shenanigans. Compiler needs to be convinced to dereference in most
 3 // cases and circumventing the type system (compiler's ability to
 4 // check correctness) is fraught with errors.
 5 #include <stdio.h>
 6 int main(){
 7     int a = 5;                      // int
 8     double x = 1.2345;              // double
 9     void *ptr;                     // pointer to anything
10
11     ptr = &a;
12     int b = *((int *) ptr);        // typecast to convince compiler to deref
13     printf("%d\n",b);
14
15     ptr = &x;
16     double y = *((double *) ptr); // typecast to convince compiler to deref
17     printf("%f\n",y);
18
19     int c = *((int *) ptr);        // kids: this is why types are useful
20     printf("%d\n",c);
21
22     return 0;
23 }
>> gcc void_pointer.c
>> ./a.out
5
1.234500
309237645    # interpreting half of a double as an integer
```

## Byte-level Picture of Memory at main() line 20

BYTE		VALUE	VALUE	VAL	int VALUE	
ADDR	SYM	TYPED	BINARY	HEX	in DECIMAL	
#2043	ptr	v	0000 0000	0x00		void *ptr occupies
#2042	ptr	v	0000 0000	0x00		8 contiguous bytes
#2041	ptr	v	0000 0000	0x00		from #2036-#2043
#2040	ptr	v	0000 0000	0x00	0	and currently points
#2039	ptr	v	0000 0000	0x00		at #2028; the bits/bytes
#2038	ptr	v	0000 0000	0x00		there must be typecast
#2037	ptr	v	0000 0111	0x07		in order to dereference
#2036	ptr	#2028	1110 1100	0xec	2028	
#2035	x	v	0011 1111	0x3f		double x occupies
#2034	x	v	1111 0011	0xf3		8 contiguous bytes
#2033	x	v	1100 0000	0xc0		from #2028-#2035
#2032	x	v	1000 0011	0x83	1072939139	but ptr points to
#2031	x	v	0001 0010	0x12		#2028 and prints bytes
#2030	x	v	0110 1110	0x6e		#2028-2031 as a 4-byte
#2029	x	v	1001 0111	0x97		integer
#2028	x	1.2345	1000 1101	0x8d	309237645	
#2027	a	v	0000 0000	0x00		int a occupies
#2026	a	v	0000 0000	0x00		4 contiguous bytes
#2025	a	v	0000 0000	0x00		from #2024-#2027
#2024	a	5	0000 0101	0x05	5	

## Answers: Legacy of the Void (Pointer)

- ▶ The big weird integer 309237645 printed at the end is because...
  - ▶ ptr points at a memory location with a double
  - ▶ The compiler is “tricked” into treating this location as storing int data via the `(int *)` typecast
  - ▶ Integer vs Floating bit layout is **very different**; we’ll study this difference (briefly) later
  - ▶ Compiler generates low level instructions to move 4 bytes of the double data to an integer location
  - ▶ Both size and bit layout don’t match
- ▶ Since this is possible to do on a Von Neumann machine C makes it possible
- ▶ This does not mean it is a good idea: `void_pointer.c` illustrates **weird code** that is atypical and error-prone
- ▶ Avoid `void *` pointers when possible, take care when you must use them (there are *many times* you must use them in C)

# But wait, there're more types...

## Unsigned Variants

Trade sign for larger positives

Name	Range
unsigned char	0 to 255
unsigned short	0 to 65,535
unsigned int	0 to 4,294,967,295
unsigned long	0 to... big, okay?

After our C crash course, we will discuss representation of integers with bits and relationship between signed / unsigned integer types

## Fixed Width Variants since C99

Specify size / properties

int8_t	signed integer type with width of exactly 8, 16, 32 and 64 bits respectively
int16_t	
int32_t	
int64_t	
int_fast8_t	fastest signed integer type with width of at least 8, 16, 32 and 64 bits respectively
int_fast16_t	
int_fast32_t	
int_fast64_t	
int_least8_t	smallest signed integer type with width of at least 8, 16, 32 and 64 bits respectively
int_least16_t	
int_least32_t	
int_least64_t	
intmax_t	maximum width integer type
intptr_t	integer type capable of holding a pointer
uint8_t	unsigned integer type with width of exactly 8, 16, 32 and 64 bits respectively
uint16_t	
uint32_t	
uint64_t	
uint_fast8_t	fastest unsigned integer type with width of at least 8, 16, 32 and 64 bits respectively
uint_fast16_t	
uint_fast32_t	
uint_fast64_t	
uint_least8_t	smallest unsigned integer type with width of at least 8, 16, 32 and 64 bits respectively
uint_least16_t	
uint_least32_t	
uint_least64_t	
uintmax_t	maximum width unsigned integer type
uintptr_t	unsigned int capable of holding pointer

# Arrays in C

- ▶ Array: a continuous block of homogeneous data
- ▶ Automatically allocated by the compiler/runtime with a **fixed size**<sup>1</sup>
- ▶ Support the familiar [ ] syntax
- ▶ Refer to a single element via arr[3]
- ▶ **Bare name arr** is the **memory address where array starts**

```
{  
    int x      = 42;  
    int *p     = &x;  
    int a[3]   = {10,20,30};  
    int *ap    = a;  
}  
  
| Addr   | Type   | Sym   | Val  |  
|-----+-----+-----+-----|  
| #4948 | int*   | ap    | #4936 |  
| #4944 | int    | a[2]  | 30   |  
| #4940 | int    | a[1]  | 20   |  
| #4936 | int    | a[0]  | 10   |  
| #4928 | int*   | p     | #4924 |  
| #4924 | int    | x     | 42   |
```

<sup>1</sup> Modern C supports variable sized arrays in the stack but we will not use them until much later in the class. They are NOT a general substitute for heap-allocation with `malloc()`

# Arrays and Pointers are Related with Subtle differences

Property	Pointer	Array
Declare like...	<code>int *p; // rand val</code> <code>int *p = &amp;x;</code> <code>int *p = q;</code>	<code>int a[5]; // rand vals</code> <code>int a[] = {1, 2, 3};</code> <code>int a[2] = {2, 4};</code>
Refers to a...	Memory location	Memory location
Which could be..	Anywhere	Fixed location
Location ref is	Changeable	Not changeable
Location...	Assigned by coder	Determined by compiler
Has at it..	One or more thing	One or more thing
Brace index?	Yep: <code>int z = p[0];</code>	Yep: <code>int z = a[0];</code>
Dereference?	Yep: <code>int y = *p;</code>	Nope
Arithmetic?	Yep: <code>p++;</code>	Nope
Assign to array?	Yep: <code>int *p = a;</code>	Nope
Interchangeable	<code>doit_a(int a[]);</code> <code>int *p = ...</code> <code>doit_a(p);</code>	<code>doit_p(int *p);</code> <code>int a[] = {1,2,3};</code> <code>doit_p(a);</code>
Tracks num elems	NOPE  Nada, nothin, nope	NOPE  No <code>a.length</code> or <code>length(a)</code>

## Example: pointer\_v\_array.c

```
1 // pointer_v_array.c: Demonstrate equivalence of pointers and
2 // arrays. An array is represented by its starting address so can be
3 // passed to a function taking a pointer as such. Similarly, a pointer
4 // value is an address so can be passed to a function taking an array
5 // argument. printf("%p") prints pointer values in hexadecimal format.
6
7 #include <stdio.h>
8
9 void print0_arr(int a[]){      // print 0th element of a
10    printf("%p: %d\n", a, a[0]); // address and 0th elem
11 }
12 void print0_ptr(int *p){      // print int pointed at by p
13    printf("%p: %d\n", p, *p); // address and 0th elem
14 }
15 int main(){
16    int *p = NULL;            // declare a pointer, points nowhere
17    printf("%p: %p\n", &p, p); // print address/contents of p
18    int x = 21;               // declare an integer
19    p = &x;                  // point p at x
20    print0_arr(p);           // pointer as array
21    int a[] = {5,10,15};     // declare array, auto size
22    print0_ptr(a);           // array as pointer
23    //a = p;                 // can't change where array points
24    p = a;                  // point p at a
25    print0_ptr(p);
26    return 0;
27 }
```

# Execution of Code/Memory 1

```
1 void print0_arr(int a[]){
2     printf("%p: %d\n", a, a[0])
3 }
4 void print0_ptr(int *p){
5     printf("%p: %d\n", p, *p);
6 }
7 int main(){
8     int *p = NULL;
9     printf("%p: %p\n", &p, p);
<1> 10    int x = 21;
<2> 11    p = &x;
<3> 12    print0_arr(p);
13    int a[] = {5,10,15};
14    print0_ptr(a);
15    //a = p;
<4> 16    p = a;
<5> 17    print0_ptr(p);
18    return 0;
19 }
```

# Summary of Pointer / Array Relationship

## Arrays

- ▶ Arrays are allocated by the Compiler at a **fixed location**
- ▶ **Bare name** a references is the starting address of the array
- ▶ Must use square braces `a[i]` to index into them

## Pointers

- ▶ Pointers can point to anything, can change, must be manually directed
- ▶ Can use square braces `p[i]` or deref `*p` to index into them

## Interchangeability

- ▶ In most cases, functions that require an array can be passed a pointer, functions that require a pointer can be passed an array
- ▶ Works BECAUSE array variables are passed as their starting memory address, a pointer value

## Exercise: Pointer Arithmetic

“Adding” to a pointer increases the position at which it points

- ▶ Add 1 to an `int*`: point to the next `int`, add 4 bytes
- ▶ Add 1 to a `double*`: point to next `double`, add 8 bytes

**Examine** `pointer_arithmetic.c` below. Show memory contents and what's printed on the screen

```
// pointer_arithmetic.c
1 #include <stdio.h>
2 void print_ptr(int *q){
3     printf("%p: %d\n", q, *q);
4 }
5 int main(){
6     int x = 21;
7     int *p;
8     int a[] = {5,10,15};
9     p = a;
10    print_ptr(p);
<1> 11    p = a+1;
12    print_ptr(p);
<2> 13    p++;
14    print_ptr(p);
<3> 15    p+=2;
16    print_ptr(p);
<4> 17    return 0;
18 }
```

# Answers: Pointer Arithmetic

```
5 int main(){
6     int x = 21;
7     int *p;
8     int a[] = {5,10,15};
9     p = a;
10    print_ptr(p);
<1> 11    p = a+1;
12    print_ptr(p);
<2> 13    p++;
14    print_ptr(p);
<3> 15    p+=2;
16    print_ptr(p);
<4> 17    return 0;
18 }
```

<2>

Addr	Type	Sym	Val	SCREEN:
#4948	?	?	?	4940: 10
#4944	int	a[2]	15	
#4940	int	a[1]	10	
#4936	int	a[0]	5	
#4928	int*	p	#4940	
#4924	int	x	21	

<3>

Addr	Type	Sym	Val	SCREEN:
#4948	?	?	?	4940: 10
#4944	int	a[2]	15	4944: 15
#4940	int	a[1]	10	
#4936	int	a[0]	5	
#4928	int*	p	#4944	
#4924	int	x	21	

<4>

Addr	Type	Sym	Val	SCREEN:
#4952	?	?	?	4940: 10
#4948	?	?	?	4944: 15
#4944	int	a[2]	15	4952: ???
#4940	int	a[1]	10	
#4936	int	a[0]	5	
#4928	int*	p	#4952	
#4924	int	x	21	

Out of bounds deref of #4952 is undefined behavior; may print random garbage values or may Segfault and killing the program.

# Pointer Arithmetic Alternatives

Alternatives to pointer arithmetic exist that improve readability

```
printf("enter 5 doubles\n");
double arr[5];
for(int i=0; i<5; i++){
    // POINTER: ick          // PREFERRED
    scanf("%lf", arr+i);    OR    scanf("%lf", &arr[i]);
}
printf("you entered:\n");
for(int i=0; i<5; i++){
    // POINTER: ick          // PREFERRED
    printf("%f ", *(arr+i)); OR    printf("%f ", arr[i]);
}
```

However, some situations benefit from pointer manipulations, often in string processing like the following:

```
// read_name.c : string processing example
char name[128];           // up to 128 chars
printf("first name: ");
scanf(" %s", name);        // read into name
int len = strlen(name);    // compute length of string
name[len] = ' ';           // replace \0 with space
printf("last name: ");
scanf(" %s", name+len+1);   // read last name at offset
printf("full name: %s\n", name);
```

# read\_name.c : String Functions + Pointer Arithmetic

Initial scanf() +  
strlen()

Overwrite null char  
with a space

Read in after space  
using scanf()

Note the null character \0 terminates “standard” strings in C, honored by standard string functions like printf(), strlen(), strcpy(), etc.

# Strings are Character Arrays

## Conventions

- ▶ Convention in C is to use character arrays as strings
- ▶ Terminate character arrays with the \0 null character to indicate their end

```
char str1[6] =  
{'C', 'h', 'r', 'i', 's', '\0'};
```

- ▶ Null termination done by compiler for string constants

```
char str2[6] = "Chris";  
// is null terminated
```

- ▶ Null termination done by most standard library functions like scanf()

## Be aware

- ▶ fread() does not append nulls when reading binary data
- ▶ Manually manipulating a character array may overwrite ending null

## String Library

- ▶ Include with <string.h>
- ▶ Null termination expected
- ▶ strlen(s): length of string
- ▶ strcpy(dest, src): copy chars from src to dest
- ▶ Limited number of others

# Allocating Memory with malloc() and free()

## Dynamic Memory

- ▶ Most C data has a fixed size: single vars or arrays with sizes specified at compile time
- ▶ `malloc(nbytes)` is used to manually allocate memory
  - ▶ single arg: number of bytes of memory
  - ▶ frequently used with `sizeof()` operator
  - ▶ returns a `void*` to bytes found or `NULL` if not enough space could be allocated
- ▶ `free()` is used to release memory

```
// malloc_demo.c
#include <stdio.h>
#include <stdlib.h> // malloc / free
int main(){
    printf("how many ints: ");
    int len;
    scanf(" %d",&len);

    int *nums = malloc(sizeof(int)*len);

    printf("initializing to 0\n");
    for(int i=0; i<len; i++){
        nums[i] = 0;
    }
    printf("enter %d ints: ",len);
    for(int i=0; i<len; i++){
        scanf(" %d",&nums[i]);
    }
    printf("nums are:\n");
    for(int i=0; i<len; i++){
        printf("[%d]: %d\n",i,nums[i]);
    }
    free(nums);
    return 0;
}
```

## Optional Exercise: Allocation Sizes

### How Big

How many bytes allocated?

How many elements in the array?

```
char    *a = malloc(16);
char    *b = malloc(16*sizeof(char));
int     *c = malloc(16);
int     *d = malloc(16*sizeof(int));
double  *e = malloc(16);
double  *f = malloc(16*sizeof(double));
int    **g = malloc(16);
int    **h = malloc(16*sizeof(int*));
```

### Allocate / Deallocate

- ▶ Want an array of ints called ages, quantity 32
- ▶ Want an array of doubles called dps, quantity is in variable int size
- ▶ Deallocate ages / dps

How many bytes CAN be allocated?

- ▶ Examine malloc\_all\_memory.c

## Answers: Allocation Sizes

```
char    *a = malloc(16);           // 16
char    *b = malloc(16*sizeof(char)); // 16
int     *c = malloc(16);           // 16
int     *d = malloc(16*sizeof(int)); // 64
double  *e = malloc(16);           // 16
double  *f = malloc(16*sizeof(double)); // 128
int     **g = malloc(16);          // 16
int     **h = malloc(16*sizeof(int*)); // 128

int *ages = malloc(sizeof(int)*32);
int size = ...;
double *dps = malloc(sizeof(double)*size);

free(ages);
free(dps);
```

# Compile and Runtime vs Memory Management

## Compile Time Sizes

- ▶ Some sizes are known at **Compile Time**
- ▶ Compiler can calculate, sizes of fixed variables, arrays, sizes of stack frames for function calls and **automatically allocate** them
- ▶ Most of these are automatically managed on the **function call stack** and don't require use of `malloc()` / `free()`

## Run Time Sizes

- ▶ Compiler can't predict the future, at **Run Time** programs must react to
  - ▶ Typed user input like names, Size of a file that is to be read
  - ▶ Elements to be added to a data structure
  - ▶ Memory allocated in one function and returned to another
- ▶ As these things are determined, `malloc()` is used to allocate memory in the **heap**, when it is finished `free()` it

## Common Misconception: `sizeof(thing)`

- ▶ `sizeof(thing)` determines the **Compile Time Size** of `thing` from C source, encodes size in executable program

- ▶ Useful when `malloc()`'ing stuff as in

```
int *arr = malloc(count * sizeof(int));
```

- ▶ **NOT USEFUL** for size of arrays/strings

```
int *arr = ...;
int nelems = sizeof(arr); // always 8 on 64-bit systems
// REASON: arr is an (int *) and pointers are 8 bytes big
double darr[4] = {};
int len = sizeof(darr); // always 32 as in 32 bytes
```

- ▶ To determine the size of arrays, must be given size OR have an ending sentinel value

- ▶ Strings commonly use `strlen()` to determine length:

```
char *str = "Hello world!\n";
int len = strlen(str); // 13
```

See `sizeof_arrays.c` for some modest examples

# The 4 Logical Regions of Program Memory

- ▶ Running program typically has 4 regions of memory
  1. **Stack**: automatic, push/pop with function calls
  2. **Heap**: malloc() / free()
  3. **Global**: variables outside functions, static vars
  4. **Text**: Program instructions in Binary
- ▶ Stack grows toward Heap, a collision results in *stack overflow*
- ▶ Global and Text regions usually fixed in size
- ▶ “Logical Regions” for Humans to organize their programs; no physical differences for regions

# Memory Tools on Linux

The Valgrind Logo alluding to the Quixotic battle against the Dragon of memory errors

## Valgrind<sup>2</sup>: Suite of tools including Memcheck

- ▶ Catches most memory errors<sup>3</sup>
  - ▶ Use of uninitialized memory
  - ▶ Reading/writing memory after it has been free'd
  - ▶ Reading/writing off the end of malloc'd blocks
  - ▶ Memory leaks
- ▶ Source line where problem arose (but not its cause)
- ▶ Super easy to use: `valgrind ./program ...`
- ▶ Slows execution of program way down

---

<sup>2</sup><http://valgrind.org/>

<sup>3</sup><http://en.wikipedia.org/wiki/Valgrind>

## Examine: Valgrind in Action

Analyze Valgrind's errors for common mistakes in `badmemory.c`

```
# Compile with debugging enabled: -g
>> gcc -g badmemory.c

# run program under valgrind
>> valgrind ./a.out

Link: [Description of common Valgrind Error Messages](#)

## Exercise: free()'ing in the Wrong Spot

Common use for `malloc()` is for one function to allocate memory and return its location to another function (such as in P1).

Question becomes **when to free()** such memory.

Program to the right is buggy,  
produces following output on one  
system

```
> gcc free_twice.c
> ./a.out
ones[0] is 0
ones[1] is 0
ones[2] is 1
ones[3] is 1
ones[4] is 1
```

```
1 int *ones_array(int len){
2     int *arr = malloc(sizeof(int)*len);
3     for(int i=0; i<len; i++){
4         arr[i] = 1;
5     }
6     free(arr);
7     return arr;
8 }
9
10 int main(){
11     int *ones = ones_array(5);
12     for(int i=0; i<5; i++){
13         printf("ones[%d] is %d\n",i,ones[i]);
14     }
15
16     free(ones);
17     return 0;
18 }
```

- ▶ Why does this bug happen?
- ▶ How can it be fixed?
- ▶ Answers in `free_twice.c`

## Answers: free()'ing in the Wrong Spot

- ▶ Once a malloc()'d area is free()'d, it is no longer valid
- ▶ Don't free() data that is the return value of a function
- ▶ Never free() twice

```
> gcc -g free_twice.c
> a.out
ones[0] is 0
ones[1] is 0
ones[2] is -1890717680
ones[3] is 22008
ones[4] is 1
free(): double free detected in tcache 2
Aborted (core dumped)
```

```
> valgrind a.out
==10125== Memcheck, a memory error detector
...
==10125== Invalid free()
==10125== at 0x48399AB: free
==10125== by 0x10921A: main (free_twice.c:24)
```

```
9 int *ones_array(int len){
10    int *arr = malloc(sizeof(int)*len);
11    for(int i=0; i<len; i++){
12        arr[i] = 1;
13    }
14    //free(arr); // should not free an array
15    return arr; // being returned
16 }
17
18 int main(){
19    int *ones = ones_array(5);
20    for(int i=0; i<5; i++){
21        printf("ones[%d] is %d\n", i, ones[i]);
22    }
23
24    free(ones); // later free makes
25    return 0; // more sense
26 }
```

Note that the Valgrind output gives an **exact line number** where the problem occurs but this is **not the line to change** to fix the problem.

# Answers: free()'ing in the Wrong Spot

[INCORRECT 1: Before ones\_array() calls free()]

[INCORRECT 2: ones\_array() calls free()]

[INCORRECT 3: ones\_array() returns free()'d array]

[CORRECT 1: ones\_array() before return, no free()]

[CORRECT 2: ones\_array() returns valid array]

free\_twice.c Program

ABOVE: Incorrect free version free()'s array before returning leading to main() getting a memory area that has no longer valid and has been marked for re-use by free().

BELOW: Corrected version which comments out the free() call in ones\_array(); a valid memory area is returned which is printed by main() and then free()'d

# structs: Heterogeneous Groupings of Data

- ▶ Arrays are homogenous: all elements the same type
- ▶ structs are C's way of defining heterogenous data
- ▶ Each **field** can be a different kind
- ▶ One instance of a struct has all fields
- ▶ Access elements with 'dot' notation
- ▶ Several syntaxes to declare, we'll favor modern approach
- ▶ Convention: types have `_t` at the end of their name to help identify them (not a rule but a good idea)

```
typedef struct{ // declare type
    int     an_int;
    double  a_doub;
    char    the_car;
    int     my_arr[6];
} thing_t;

thing_t a_thing;      // variable
a_thing.an_int      = 5;
a_thing.a_doub      = 9.2;
a_thing.the_char    = 'c';
a_thing.my_arr[2]   = 7;
int i = a_thing.an_int;

thing_t b_thing = { // variable
    .an_int = 15,           // initialize
    .a_doub = 19.2,         // all fields
    .the_char = 'D',
    .my_arr = {17, 27, 37,
               47, 57, 67}
};
```

# struct Ins/Outs

## Recursive Types

- ▶ structs can have pointers to their same kind
- ▶ Syntax is a little wonky

```
vvvvvvvvvvvvv
typedef struct node_struct {
    char data[128];
    struct node_struct *next;
} node_t;
```

## Arrow Operator

- ▶ Pointer to struct, want to work with a field
- ▶ Use 'arrow' operator -> for this (dash/greater than)

## Dynamically Allocated Structs

- ▶ Dynamic Allocation of structs requires size calculation
- ▶ Use sizeof() operator

```
node_t *one_node =
    malloc(sizeof(node_t));
int length = 5;
node_t *node_arr =
    malloc(sizeof(node_t) * length);
node_t *node = ...;
if(node->next == NULL){ ... }
```

```
list_t *list = ...;
list->size = 5;
list->size++;
```

## Exercise: Structs in Memory

- ▶ Structs allocated in memory are laid out compactly
- ▶ Compiler may *pad* fields to place them at nice alignments (even addresses or word boundaries)

```
typedef struct {
    double x;
    int y;
    char nm[4];
} small_t;

int main(){
    small_t a =
        {.x=1.23, .y=4, .nm="hi"};
    small_t b =
        {.x=5.67, .y=8, .nm="bye"};
}
```

### Memory layout of main()

Addr	Type	Sym	Val
#1031	char	b.nm[3]	\0
#1030	char	b.nm[2]	e
#1029	char	b.nm[1]	y
#1028	char	b.nm[0]	b
#1024	int	b.y	8
#1016	double	b.x	5.67
#1015	char	a.nm[3]	?
#1014	char	a.nm[2]	\0
#1013	char	a.nm[1]	i
#1012	char	a.nm[0]	h
#1008	int	a.y	4
#1000	double	a.x	1.23

### Result of?

```
scanf("%d", &a.y); // input 7
scanf("%lf", &b.x); // input 9.4
scanf("%s", b.nm); // input yo
```

## Answers: Structs in Memory

```
scanf("%d", &a.y); // input 7
scanf("%lf", &b.x); // input 9.4
scanf("%s", b_nm); // input yo
```

Addr	Type	Sym	Val Before	Val After
#1031	char	b_nm[3]	\0	\0
#1030	char	b_nm[2]	e	\0
#1029	char	b_nm[1]	y	o
#1028	char	b_nm[0]	b	y
#1024	int	b.y	8	
#1016	double	b.x	5.67	9.4
#1015	char	a_nm[3]	?	
#1014	char	a_nm[2]	\0	
#1013	char	a_nm[1]	i	
#1012	char	a_nm[0]	h	
#1008	int	a.y	4	7
#1000	double	a.x	1.23	

# Structs: Dots vs Arrows

Newcomers wonder when to use Dots vs Arrows

- ▶ Use Dot (`s.field`) with an **Actual** struct
- ▶ Use Arrow (`p->field`) for a **Pointer** to a struct

```
small_t small;          // struct: 16 bytes
small_t *sptr;          // pointer: 8 bytes

sptr = &small;          // point at struct

small.x    = 1.23;       // actual struct
sptr->x   = 4.56;       // through pointer
(*sptr).x = 4.56;       // ICK: not preferred

small.y   = 7;           // actual struct
sptr->y   = 11;          // through pointer

small.nm[0] = 'A';       // through struct
sptr->nm[1] = 'B';       // through pointer
sptr->nm[2] = '\0';      // through pointer
```

Memory at end of code on left

Addr	Sym	Value
#2072	...	...
#2064	sptr	#2048
#2063	small.nm[3]	?
#2062	small.nm[2]	\0
#2061	small.nm[1]	B
#2060	small.nm[0]	A
#2056	small.y	11
#2048	small.x	4.56

## read\_structs.c: malloc() and scanf() for structs

```
1 // Demonstrate use of pointers, malloc() with structs, scanning
2 // structs fields
3
4 #include <stdlib.h>
5 #include <stdio.h>
6
7 typedef struct {          // simple struct
8     double x;      int y;    char nm[4];
9 } small_t;
10
11 int main(){
12     small_t c;           // stack variable
13     small_t *cp = &c;       // address of stack var
14     scanf("%lf %d %s", &cp->x, &cp->y, cp->nm); // read struct fields
15     printf("%f %d %s\n", cp->x, cp->y, cp->nm); // print struct fields
16
17     small_t *sp = malloc(sizeof(small_t)); // malloc'd struct
18     scanf("%lf %d %s", &sp->x, &sp->y, sp->nm); // read struct fields
19     printf("%f %d %s\n", sp->x, sp->y, sp->nm); // print struct fields
20
21     small_t *sarr = malloc(5*sizeof(small_t)); // malloc'd struct array
22     for(int i=0; i<5; i++){
23         scanf("%lf %d %s", &sarr[i].x, &sarr[i].y, sarr[i].nm); // read
24         printf("%f %d %s\n", sarr[i].x, sarr[i].y, sarr[i].nm); // print
25     }
26
27     free(sp);           // free single struct
28     free(sarr);         // free struct array
29     return 0;
30 }
```

# File Input and Output

- ▶ Standard C I/O functions for reading/writing file data.
- ▶ Work with text data: formatted for human reading

```
FILE *fopen(char *fname, char *mode);
// open file named fname, mode is "r" for reading, "w" for writing
// returns a File Handle (FILE *) on success
// returns NULL if not able to open file; do not fclose(NULL)

int fclose(FILE *fh);
// close file associated with fh, writes pending data to file,
// free()'s memory associated with open file
// Do not fclose(NULL)

int fscanf(FILE *fh, char *format, addr1, addr2, ...);
// read data from an open file handle according to format string
// storing parsed tokens in given addresses returns EOF if end of file
// is reached

int fprintf(FILE *fh, char *format, arg1, arg2, ...);
// prints data to an open file handle according to the format string
// and provided arguments

void rewind(FILE *fh);
// return the given open file handle to the beginning of the file.
```

Example of use in struct\_text\_io.c

# Binary Data I/O Functions

- ▶ Open/close files same way with `fopen()`/`fclose()`
- ▶ Read/write raw bytes (not formatted) with the following

```
size_t fread(void *dest, size_t byte_size, size_t count, FILE *fh);
// read binary data from an open file handle. Attempt to read
// byte_size*count bytes into the buffer pointed to by dest.
// Returns number of bytes that were actually read

size_t fwrite(void *src, size_t byte_size, size_t count, FILE *fh);
// write binary data to an open file handle. Attempt to write
// byte_size*count bytes from buffer pointed to by src.
// Returns number of bytes that were actually written
```

See examples of use in `struct_binary_io.c`

## Tradeoffs between Binary and Textual Files

- ▶ Binary files usually smaller than text and can be directly read into memory but NOT easy on the eyes
- ▶ Text data more readable but more verbose, must be parsed and converted to binary numbers

## Optional Exercise: Common C operators

Arithmetic + - \* / %

Integer/Floating Division

Predict values for each variable

Comparison == > < <= >= !=

Logical && || !

```
int q = 9 / 4;
```

Memory & and \*

```
int r = 9 % 4;
```

Compound += -= \*= /= ...

```
double x = 9 / 4;
```

```
double y = (double) 9 / 4;
```

```
double z = ((double)9) / 4;
```

```
double w = 9.0 / 4;
```

```
double t = 9 / 4.0;
```

```
int a=9, b=4;
```

```
double t = a / b;
```

Bitwise Ops

Will discuss soon

```
int x = y << 3;
```

```
int z = w & t;
```

```
long r = x | z;
```

Conditional (ternary) Operator

```
double x = 9.95;
```

```
int y = (x < 10.0) ? 2 : 4;
```

## Answers: Integer vs Floating Division

Integer versus real division: **values** for each of these are...

```
int q = 9 / 4;           // quotient 2
int r = 9 % 4;           // remainder 1
double x = 9 / 4;        // 2.0 (int quotient first)
double y = (double) 9 / 4; // 2.25
double z = ((double)9) / 4; // 2.25
double w = 9.0 / 4;       // 2.25
double t = 9 / 4.0;       // 2.25
int a=9, b=4;
double t = a / b;         // 2.0 (int quotient)
```

# C Control Structures

## Looping/Iteration

```
// while loop
while(truthy){
    stuff;
    more stuff;
}
```

```
// for loop
for(init; truthy; update){
    stuff;
    more stuff;
}
```

```
// do-while loop
do{
    stuff;
    more stuff;
} while( truthy );
```

## Conditionals

```
// simple if
if( truthy ){
    stuff;
    more stuff;
}
```

```
// chained exclusive if/elses
if( truthy ){
    stuff;
    more stuff;
}
else if(other){
    stuff;
}
else{
    stuff;
    more stuff;
}
```

```
// ternary ? : operator
int x = (truthy) ? yes : no;
```

# Jumping Around in Loops

## break: often useful

```
// break statement ends loop
// only valid in a loop
while(truthy){
    stuff;
    if( istrue ){
        something;
        break;-----+
    }           |
    more stuff; |
}
after loop; <--+
```

```
// break ends inner loop,
// outer loop advances
for(int i=0; i<10; i++){
    for(int j=0; j<20; j++){
        printf("%d %d ",i,j);
        if(j == 7){
            break;-----+
        }
    }
    printf("\n");<--+
}
```

## continue: occasionally useful

```
// continue advances loop iteration
// does update in for loops
```

```
+-----+
V      |
for(int i=0; i<10; i++){
    printf("i is %d\n",i);
    if(i % 3 == 0){
        continue;-----+
    }
    printf("not div 3\n");
}
```

Prints  
i is 0  
i is 1  
not div 3  
i is 2  
not div 3  
i is 3  
i is 4  
not div 3  
...

# Really Jumping Around: goto

- ▶ Machine-level control involves jumping to different instructions
- ▶ C exposes this as
  - ▶ somewhere: label for code position
  - ▶ goto somewhere; jump to that location
- ▶ `goto_demo.c` demonstrates a loop with gotos
- ▶ **Avoid** goto unless you have a compelling motive
- ▶ Beware spaghetti code... and raptor attacks...

```
1 // goto_demo.c: control flow with goto
2 // Low level assembly jumps are similar
3 #include <stdio.h>
4 int main(){
5     int i=0;
6     beginning:           // label for gotos
7     printf("i is %d\n",i);
8     i++;
9     if(i < 10){
10         goto beginning; // go back
11     }
12     goto ending;        // go forward
13     printf("print me please!\n");
14     ending:             // label for goto
15     printf("i ends at %d\n",i);
16     return 0;
17 }
```

XKCD #292

# switch()/case: The **worst** control structure

- ▶ switch/case allows jumps based on an integral value
- ▶ Frequent source of errors
- ▶ switch\_demo.c shows some features
  - ▶ use of break
  - ▶ fall through cases
  - ▶ default catch-all
  - ▶ Use in a loop
- ▶ May enable some small compiler optimizations
- ▶ Almost **never** worth correctness risks: one good use in my experience
- ▶ **Favor if/else if/else unless compelled otherwise**

```
1 // switch_demo.c: peculiarities of switch/case
2 #include <stdio.h>
3 int main(){
4     while(1){
5         printf("enter a char: ");
6         char c;
7         scanf(" %c",&c); // ignore preceding spaces
8         switch(c){ // switch on read char
9             case 'j': // entered j
10                printf("Down line\n");
11                break; // go to end of switch
12            case 'a': // entered a
13                printf("little a\n");
14            case 'A': // entered A
15                printf("big A\n");
16                printf("append mode\n");
17                break; // go to end of switch
18            case 'q': // entered q
19                printf("Quitting\n");
20                return 0; // return from main
21            default: // entered anything else
22                printf("other '%c'\n",c);
23                break; // go to end of switch
24        } // end of switch
25    }
26    return 0;
27 }
```

# A Program is Born: Compile, Assemble, Link, Load

- ▶ Write some C code in `program.c`
- ▶ Compile it with toolchain like GNU Compiler Collection  
`gcc -o program prog.c`
- ▶ Compilation is a multi-step process
  - ▶ Check syntax for correctness/errors
  - ▶ Perform optimizations on the code if possible
  - ▶ Translate result to **Assembly Language** for a specific target processor (Intel, ARM, Motorola)
  - ▶ **Assemble** the code into **object code**, binary format (ELF) which the target CPU understands
  - ▶ **Link** the binary code to any required libraries (e.g. printing) to make an **executable**
- ▶ Result: executable `program`, but...
- ▶ To run it requires a **loader**: program which copies executable into memory, initializes any shared library/memory references required parts, sets up memory to refer to initial instruction

## Review Exercise: Memory Review

1. How do you allocate memory on the Stack? How do you de-allocate it?
2. How do you allocate memory dynamically (on the Heap)? How do you de-allocate it?
3. What other parts of memory are there in programs?
4. How do you declare an array of 8 integers in C? How big is it and what part of memory is it in?
5. Describe several ways arrays and pointers are similar.
6. Describe several ways arrays and pointers are different.
7. Describe how the following two arithmetic expressions differ.

```
int x=9, y=20;
```

```
int *p = &x;
```

```
x = x+1;
```

```
p = p+1;
```

## Answers: Memory Review

1. How do you allocate memory on the Stack? How do you de-allocate it?

*Declare local variables in a function and call the function. Stack frame has memory for all locals and is de-allocated when the function finishes/returns.*

2. How do you allocate memory on the Heap? How do you de-allocate it?

*Make a call to `ptr = malloc(nbytes)` which returns a pointer to the requested number of bytes. Call `free(ptr)` to de-allocate that memory.*

3. What other parts of memory are there in programs?

*Global area of memory has constants and global variables. Text area has binary assembly code for CPU instructions.*

4. How do you declare an array of 8 integers in C? How big is it and what part of memory is it in?

*An array of 8 ints will be 32 bytes big (usually).*

*On the stack: `int arr[8];` De-allocated when function returns.*

*On the heap: `int *arr = malloc(sizeof(int) * 8);` Deallocated with `free(arr);`*

## Answers: Memory Review

5. Describe several ways arrays and pointers are similar.

*Both usually encoded as an address, can contain 1 or more items, may use square brace indexing like arr[3] = 17; Interchangeable as arguments to functions. Neither tracks size of memory area referenced.*

6. Describe several ways arrays and pointers are different.

*Pointers may be deref'd with \*ptr; can't do it with arrays. Can change where pointers point, not arrays. Arrays will be on the Stack or in Global Memory, pointers may also refer to the Heap.*

7. Describe how the following two arithmetic expressions differ.

```
int x=9, y=20;      // x at #1024
int *p = &x;        // p hold VALUE #1024 (points at x)
x = x+1;           // x is now 10:    normal arithmetic
p = p+1;           // p is now #1028: pointer arithmetic
                    // may or may not point at y
```
