Control Flow in Assembly and the Instruction Pointer

Instruction Pointer Register

- %rip: special register (not general purpose) referred to as the Instruction Pointer or Program Counter
- %rip contains main memory address of next assembly instruction to execute
- After executing an instruction, %rip automatically updates to the subsequent instruction
 OR in a Jump instruction, %rip changes non-sequentially
- ▶ Do not add/subtract with %rip via addq/subq: %rip automatically updates after each instruction

Jump Instructions

- ► **Labels** in assembly indicate jump targets like .LOOP:
- Unconditional Jump: always jump to a new location by changing %rip non-sequentially
- Comparison / Test: Instruction, sets EFLAGS bits indicating relation between registers/values (greater, less than, equal)
- ➤ Conditional Jump: Jumps to a new location if certain bits of EFLAGS are set by changing %rip non-sequentially; otherwise continues sequential execution

Exercise: Loop Sum with Instruction Pointer (rip)

- Can see direct effects on rip in disassembled code
- rip increases corresponding to instruction length
- Jumps include address for next rip

61c: c3

```
// C Code equivalent
long sum=0, i=1, lim=100;
while(i<=lim){
   sum += i;
   i++;
}
return sum;</pre>
```

rip 61c -> return address

```

Disassembling Binaries

- Binaries hard to read on their own
- ▶ Many tools exist to work with them, notably objdump on Unix
- Can disassemble binary: show "readable" version of contents

```
> gcc -Og loop.s
                              # COMPILE AND ASSEMBLE
> file a.out
a.out: ELF 64-bit LSB pie executable, x86-64, version 1 (SYSV).
> objdump -d a.out
                              # DISASSEMBLE BINARY
        file format elf64-x86-64
a.out.:
Disassembly of section .text:
0000000000001119 <main>:
   1119: 48 c7 c0 00 00 00 00
                                             $0x0, %rax
                                      mov
   1120: 48 c7 c1 01 00 00 00

```

FLAGS: Condition Codes Register

- ► Most CPUs have a special register with "flags" for various conditions: each bit is True/False for a specific condition
- ▶ In x86-64 this register goes by the following names

Name	Width	Notes	
FLAGS	16-bit	Most important bits in first 16	
EFLAGS	32-bit	Name shown in gdb	
RFLAGS	64-bit	Not used normally	

- Bits in FLAGS register are automatically set based on results of other operations
- Pertinent examples with conditional execution

Bit	Abbrev	Name	Description
0	CF	Carry flag	Set if last op caused Unsigned overflow
6	ZF	Zero flag	Set if last op yielded a 0 result
7	SF	Sign flag	Set if last op yielded a negative
8	TF	Trap flag	Used by gdb to stop after one ASM instruction
9	IF	Interrupt flag	1: handle hardware interrupts, 0: ignore them
11	OF	Overflow flag	Set if last op caused SIGNED overflow/underflow

Comparisons and Tests

Set the EFLAGS register by using comparison instructions

Name	Instruction	Examples	Notes
Compare	cmpX B, A	cmpl \$1,%eax	Like if(eax > 1){}
	Like: A - B	cmpq %rsi,%rdi	Like if(rdi > rsi){}
Test	testX B, A	testq %rcx,%rdx	Like if(rdx & rcx){}
	Like: A & B	testl %rax,%rax	Like if(rax){}

- Immediates like \$2 must be the first argument B
- ▶ B,A are NOT altered with cmp/test instructions
- ► EFLAGS register IS changed by cmp/test to indicate less than, greater than, 0, etc.

Jump Instruction Summary

All control structures implemented using combination of Compare/Test + Jump instructions.

Instruction	Jump Condition	FLAGS
jmp LAB	Unconditional jump	-
je LAB	Equal / zero	ZF
jz LAB		ZF
jne LAB	Not equal $/$ non-zero	! ZF
jnz LAB		! ZF
js LAB	Negative ("signed")	SF
jns LAB	Nonnegative	!SF
jg LAB	Greater-than signed	!(SF xor OF) and !ZF
jge LAB	Greater-than-equal signed	!(SF xor OF)
jl LAB	Less-than signed	(SF xor !OF)
jle LAB	Less-than-equal signed	(SF xor !OF) or !ZF
ja LAB	Above unsigned	!CF and !ZF
jae LAB	Above-equal unsigned	!CF
jb LAB	Below unsigned	CF and !ZF
jbe LAB	Below-equal unsigned	CF
jmp *OPER	Unconditional jump to	-
	variable address	

Examine: Compiler Comparison Inversion

- Often compiler inverts comparisons
- i < n becomes cmpX /
 jge (jump greater/equal)</pre>
- i == 0 becomes cmpX /
 jne (jump not equal)
- ► This allows "true" case to fall through immediately
- Depending on structure, may have additional jumps
 - if(){ .. } usually has a single jump
 - if(){} else {} may have a couple

```
## Assembly translation of
## if(rbx >= 2){
## rdx = 10:
## }
## else{
## rdx = 5:
## }
## return rdx;
  cmpq $2,%rbx
                   # compare: rbx-2
        .LESSTHAN
                   # goto less than
 ## if(rbx \geq 2){
 movq $10, %rdx # greater/equal
 ## }
  qmj
        . AFTER
.LESSTHAN:
 ## else{
 movq $5,%rdx # less than
 ## }
. AFTER:
 ## rdx is 10 if rbx >= 2
 ## rdx is 5 otherwise
 movq %rdx, %rax
 ret.
```

Logical And / Or in Assembly

Logical boolean operators like a && b and $x \mid \mid y$ translate sequences of compare/test instructions followed by conditional jumps. See andcond_asm.s and nestedcond_asm.s

```
// andcond.c
int andcond(int edi){
  int ecx;
  if(edi >= 2 && edi <= 10){
    ecx = 10;
  }
  else{
    ecx = 5;
  }
  return ecx;
}</pre>
```

C Boolean expressions may "short circuit": never execute code associated with later parts of the condition if early part resolves conditional

```
### andcond asm.s
.text
.global andcond
andcond:
cmpl $2,%edi # compare: edi-2
  il .ELSE
  cmpl $10, %edi # compare: edi-10
  ig .ELSE
  ## if(edi >= 2 && edi <= 10){
  movl $10.%ecx # greater/equal
  ## }
  jmp
       . AFTER
. ELSE:
  ## else{
  movl $5,%ecx # less than
  ## }
.AFTER:
  movl %ecx.%eax
  ret.
```

Exercise: The test Instruction

```
main:
                     $0, %eax
 2
            movl
 3
            Tvom
                     $5,%edi
 4
            movl
                     $3,%esi
                     $0, %rdx
 5
            mova
                     $-4.%ecx
            movl
                     %edi,%edi
            test1
8
            jnz
                      . NONZERO
10
            add1
                      $20, %eax
11
12
   . NONZERO:
            test1
                     %esi.%esi
13
                      .FALSEY
14
            iz
15
            add1
                      $30, %eax
16
   .FALSEY:
17
18
            testq
                     %rdx,%rdx
19
            ie
                      .ISNULL
20
            add1
                      $40, %eax
21
   . TSNULL:
22
23
            testl
                     %ecx,%ecx
                      NONNEGATIVE
24
            ins
            1bbs
                      $50, %eax
25
26
27
    NONNEGATIVE:
```

ret

28

- ► test1 %eax,%eax uses bitwise AND to examine a register
- Selected by compiler to check for zero, NULL, negativity, etc.
- ► Followed by je / jz / jne / jnz / js / jns
- Demoed in jmp_tests_asm.s
- ► Trace the execution
- ▶ Determine final value in %eax

Answers: The test Instruction

```
1 ### From jmp_tests_asm_commented.s
 2 main:
 3
            mov1
                     $0, %eax
                                      # ear is 0
                    $5,%edi
 4
            movl
                                     # set initial vals
                    $3,%esi
 5
            movl
                                     # for registers to
            movl
                    $0.%edx
                                     # use in tests
 6
                    $-4.%ecx
 7

            testl
17
            iz
                     .FALSEY
                                      # jump on ZF same as je
            ## if(esi){
18
            addl
                     $30, %eax
19
            ## }
20
    .FALSEY:
21
22
            testq
                    %rdx,%rdx
                                     # any bits set
                     .ISNULL
                                      # same as iz: iump on ZF
23
            ie
24
            ## if(rdx != NULL){
25
            addl
                     $40, %eax
            ## }
26
    TSNIII.I.:
            testl
                    %ecx,%ecx
                                      # sign flag set on test to indicate negative results
28
                      .NONNEGATIVE
                                     # jump on !SF (not signed; e.g. positive)
29
            ins
            ## if(ecx < 0){
30
            add1
                     $50, %eax
31
32
            ## }
33
    NONNEGATIVE:
                          ## eax is return value
34
            ret
```

cmov Family: Conditional Moves

- Instruction family which copies data conditioned on FLAGS¹
- Can limit jumping in simple assignments

```
cmpq %r8,%r9
cmovge %r11,%r10 # if(r9 >= r8) { r10 = r11 }
cmovg %r13,%r12 # if(r9 > r8) { r12 = r13 }
```

- Note flags set on all Arithmetic Operations
- cmpX is like subQ: both set FLAG bits the same
- Greater than is based on the SIGN flag indicating subtraction would be negative allowing the following:

```
subq %r8,%r9 # r9 = r9 - r8
cmovge %r11,%r10 # if(r9 >= 0) { r10 = r11 }
cmovg %r13,%r12 # if(r9 > 0) { r12 = r13 }
```

 $^{^1}$ Other architectures like ARM have conditional versions of many instructions like addlt r1, r2, r3; RISC V ditches the FLAGS register in favor of jumps based on comparisons like BLT x0, x1, LOOP

Procedure Calls

Have seen basics so far:

```
main:
    call my_func # call a function
    ## arguments in %rdi, %rsi, %rdx, etc.
    ## control jumps to my_func, returns here when done
    ...

my_func:
    ## arguments in %rdi, %rsi, %rdx, etc.
    ...
    movl $0,%eax # set up return value
    ret # return from function
    ## return value in %rax
    ## returns control to wherever it came from
```

Need several additional notions

- Control Transfer to called function?
- Return back to calling function?
- Stack alignment and conventions
- Register conventions

Procedure Calls Return to Arbitrary Locations

- call instructions always transfer control to start of return_seven at line 4/5, like jmp instruction which modifies %rip
- ret instruction at line 6 must transfer control to different locations
 - 1. call-ed at line 11 ret to line 12
 - 2. call-ed at line 17 ret to line 18

ret cannot be a normal jmp

 To enable return to multiple places, record a Return
 Address when call-ing, use it when ret-urning

```
1 ### return seven asm.s

call / ret with Return Address in Stack

call Instruction

- Push the "caller" Return Address onto the stack Return address is for instruction after call
- Change rip to first instruction of the "callee" function

ret Instruction

- 1. Set rip to Return Address at top of stack
- 2. Pop the Return Address off to shrink stack

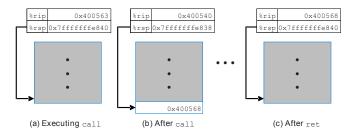

Figure: Bryant/O'Hallaron Fig 3.26 demonstrates call/return in assembly

return_seven_asm.s 1/2: Control Transfer with call

```
### BEFORE CALL
return seven:
   0x555555555139 <return seven> mov
                                          $0x7. %eax
   0x55555555513e <return seven+5> retq
main: ...
   0x555555555513f <main>
                                   sub
                                          $0x8, %rsp
=> 0x5555555555143 < main+4>
                                   callq
                                          0x5555555555139 <return seven>

                                   mov
(gdb) print $rsp --> $3 = 0x7fffffffe450
```

Warning: %rsp is important for returns

- ▶ When a function is about to return %rsp MUST refer to the memory location of the return address
- ret uses value pointed to %rsp as the return address
- Segmentation Faults often occur if %rsp is NOT the return address: attempt to fetch/execute instructions out of bounds
- Stack is often used to store local variables, stack pointer %rsp is manipulated via pushX / subq instructions to grow the stack.
- ▶ Before returning MUST shrink stack and restore %rsp to its original value via popX / addq instructions
- ► There are computer security issues associated stack-based return value we will discuss later

Messing up the Return Address

```
### return_seven_buggy_asm.s
.text
.global return_seven
return seven:
  pushq $0x42
                    # push but no pop before returning
  movl $7. %eax
                    # %rsp points to a 0x42 return address - BAD!
  ret.
I REG I
        VALUE |
                   I ADDRESS I
                                VALUE | NOTE
-----
                   |-----|
l rax l
                   | 0x77128 | 0x554210 | Ret Address |
| rsp | 0x77120 |--->| 0x77120 | 0x42 | Pushed Val
> gcc -g return_seven_buggy_asm.s
> ./a.out.
Segmentation fault (core dumped) ## definitely a memory problem
> valgrind ./a.out
                                ## get help from Valgrind

==2664132==
             at 0x42: ???
                                ## execute instruction at address 0x42??
==2664132== by 0x109149: ??? (return seven buggy asm.s:18)
==2664132== Address 0x42 is not stack'd, malloc'd or (recently) free'd
```

Valgrind reports like this often indicate failure to restore the stack pointer as happened here. If the stack grows, shrink it before returning.

Stack Alignment

- ► According to the strict x86-64 ABI, must align rsp (stack pointer) to 16-byte boundaries when calling functions
- Will often see arbitrary pushes or subtractions to align
 - Functions called with 16-byte alignment
 - call pushes 8-byte Return Address on the stack
 - ▶ At minimum, must grow stack by 8 bytes to call again
- rsp changes must be undone prior to return

- Failing to align the stack may work but may break
- ► Failing to "undo" stack pointer changes will likely result in return to the wrong spot : major problems

x86-64 Register/Procedure Convention

- ▶ Used by Linux/Mac/BSD/General Unix
- ▶ Params and return in registers if possible

Parameters and Return

```
RetVal rax / eax / ax / al
Arg 1 rdi / edi / di / dil
Arg 2 rsi / esi / si / sil
Arg 3 rdx / edx / dx / dl
Arg 4 rcx / ecx / cx / cl
Arg 5 r8 / r8d / r8w / r8b
Arg 6 r9 / r9d / r9w / r9b
Arg 7 Push into the stack
Arg 8 Push into the stack
```

C function prototype indicates number, order, type of args so it is known which registers args will be in

Caller/Callee Save

rax rcx rdx rdi rsi r8 r9 r10 r11 # 9 regs

Caller save registers: alter freely

Callee save registers: must restore these before returning

rbx rbp r12 r13 r14 r15

Stack Pointer: special considerations discussed in detail

rsp # 1 reg

6 regs

Caller and Callee Save Register Mechanics

```
main:
             # main: the calleR
   movq $21, %rdi
                  # calleR save arg 1
   movq $31, %rsi # calleR save arg 2
  movq $41, %r10 # calleR save
   movq $7, %rbx # calleE save
   movq $11, %r12 # calleE save
   call foo # foo: the calleE
          | %rdi | calleR save arg 1 |
         | %rsi | calleR save arg 2
   ##
   ##
          | %r10 | calleR save
            %rbx | calleE save
       11 | %r12 | calleE save
   cmpq $21, %rdi # unpredictable
   cmpq $7, %rbx # predictably equal
   # main MUST restore %rbx and %r12 to
   # original values as function above
   # main() expects them to be unchanged
```

CalleR Save Regs

May all change across function call boundaries. Not a problem for **Leaf Functions** which do not call any other funcs

CalleE Save Regs

Have the same values in them after a function call Using them requires saving their original values in the stack and restoring them

sumrange_asm.s

Full example of callee save regs like sumrange_c.c

Pushing and Popping the Stack

pushX data

pushq %rax

- ▶ If local variables or callee save regs are needed on the stack, can use push / pop for these
- ► Push and Pop Instructions are compound: manipulate %rsp and move data in single instruction

Grow Stack, store data at top

Like: subq \$8, %rsp; movq %rax, (%rsp)

```
pushl $25
                     Like: subq $4,%rsp; movq $25, (%rsp)
        popX data
                     Shrink Stack, restore data from it
        popl %edi
                     Like: movl (%rsp), %edi; addq $4, %rsp;
        popq %rax
                     Like: movq (%rsp), %rax; addq $8, %rsp;
main:
           %rbp
                            # save register, aligns stack
    pushq
                             # like subq $8, %rsp; movq %rbp,(%rsp)
    call
                            # call function
            sum range
    Tvom
            %eax, %ebp
                            # save answer
    call
                            # call function, ebp not affected
            sum range
            %rbp
                             # restore rbp, shrinks stack
    popq
                             # like movg (%rsp), %rbp; addg $8, %rsp
    ret
```

Exercise: Local Variables which need an Address

Compare code in files

- swap_pointers.c : familiar C code for swap via pointers
- swap_pointers_asm.s : hand-coded assembly version

Determine the following

- 1. Where are local C variables x,y stored in assembly version?
- 2. Where does the assembly version "grow" the stack?
- 3. How are the values in main() passed as arguments to swap_ptr()?
- 4. Where does the assembly version "shrink" the stack?

Exercise: Local Variables which need an Address

```
# swap_pointers_asm.s
                                            2 .text
                                              .global swap ptr
                                              swap_ptr:
                                                                (%rdi), %eax
                                            5
                                                       movl
                                                       movl
                                                                (%rsi), %edx
                                                               %edx. (%rdi)
                                                       movl
 1 // swap_pointers.c
                                                       movl
                                                               %eax, (%rsi)
   #include <stdio.h>
                                                       ret
 3
                                              .global main
   void swap ptr(int *a, int *b){
                                           11 main:
     int tmp = *a;

                                                               $8, %rsp
                                                       addq
                                                               $0, %eax
                                           26
                                                       movl
                                           27
                                                       ret
                                              .data
                                              FORMAT:
                                                       .asciz "%d %d\n"
                                           30
```

Answers: Local Variables which need an Address

- 1. Where are local C variables x, y stored in assembly version?
- 2. Where does the assembly version "grow" the stack?
- 3. How are the values in main() passed as arguments to swap_ptr()?

```
// C CODE
int x = 19, y = 31;
swap_ptr(&x, &y) // need main mem addresses for x,y
### ASSEMBLY CODE
                         # main() function
main:
          $8, %rsp # grow stack by 8 bytes
   subq
   movl $19, (%rsp) # move 19 to local variable x
   movl $31, 4(%rsp) # move 31 to local variable y
   movq %rsp, %rdi # address of x into rdi, 1st arg to swap_ptr()
   leaq
          4(%rsp), %rsi # address of y into rsi, 2nd arg to swap_ptr()
           swap_ptr
                         # call swap function
   call
```

4. Where does the assembly version "shrink" the stack?

```
addq $8, %rsp  # shrink stack by 8 bytes
movl $0, %eax  # set return value
ret
```

Diagram of Stack Variables

- Compiler determines if local variables go on stack
- ▶ If so, calculates location as rsp + offsets

```
1 // C Code: locals.c
                                      REG
                                           | VALUE | Name
2 int set_buf(char *b, int *s);
                                     -----
3 int main(){
                                     | rsp | #1024 | top of stack
4 // locals re-ordered on
                                                 | during main
5 // stack by compiler
6 int size = -1:
                                    I MEM
7 char buf[16]:
8
                                    | #1031 | h | buf[3]
   . . .
                                    | #1030 | s | buf[2]
    int x = set_buf(buf, &size);
                                    | #1029 | u | buf[1]
10
     . . .
                                    | #1028 | p | buf[0]
11 }
                                    | #1024 | -1
                                                 Isize
                                     -----
1 ## EQUIVALENT ASSEMBLY
2 main:
           $24, %rsp
     suba
                            # space for buf/size and stack alignment
3
     movl $-1,(%rsp)
                            # retAddr:8, locals: 20, padding: 4, tot: 32
                            # initialize buf and size: main line 6
            4(%rsp), %rdi
                          # address of buf arg1
     lead
     leaq 0(%rsp), %rsi # address of size arg2
     call set buf
                           # call function, aligned to 16-byte boundary
     movl %eax.%r8
                           # get return value
10
             $24, %rsp
     addq
                           # shrink stack size
11
```

Summary of Procedure Calls: ABC() calls XYZ()

ABC() Caller callq XYZ # ABC to XYZ
XYZ() Callee retq # XYZ to ABC

- ABC() "saves" any Caller Save registers it needs by either copying them into Callee Save registers or pushing them into the stack
- ABC() places up to 6 arguments in %rsi, %rdi, %rdx, ..., remaining arguments in stack
- ABC() ensures that stack is "aligned": %rsp contains an address that is evenly divisible by 16
- 4. ABC() issues the callq ABC instruction which (1) grows the stack by subtracting 8 from %rsp and copies a return address to that location and (2) changes %rip to the staring address of func
- 5. XYZ() now has control: %rip points to first instruction of XYZ()
- XYZ() may issue pushX val instructions or subq N,%rsp instructions to grow the stack for local variables
- XYZ() may freely change Caller Save registers BUT Callee Save registers it changes must be restored prior to returning.
- XYZ() must shrink the stack to its original position via popX %reg or addq N,%rsp instructions before returning.
- 9. XYZ() sets %rax / %eax / %ax to its return value if any.
- 10. XYZ() finishes, issues the retq instruction which (1) sets the %rip to the 8-byte return address at the top of the stack (pointed to by %rsp) and (2) shrinks the stack by doing addq \$8,%rsp
- 11. ABC() function now has control back with %rip pointing to instruction after call XYZ; may have a return value in %rax register
- 12. ABC() must assume all Caller Save registers have changed

History: Base Pointer rbp was Special Use

```
int bar(int, int, int);
int foo(void) {
  int x = bar(1, 2, 3);
  return x+5;
}
```

- 32-bit x86 / IA32 assembly used rbp and rsp to describe stack frames
- All function args pushed onto the stack when calling, changes both rsp and rbp
- x86-64: optimizes rbp to general purpose register, not used for stack purposes

```
# Old x86 / IA32 calling sequence: set both %esp and %ebp for function call
# Push all argumnets into the stack
foo:
   ## Set up for function call to bar()
   movl %esp,%ebp
                        # new frame for next function
   pushl 3
                        # push all arguments to
                        # function onto stack
   pushl 2
   pushl 1
                      # no regs used
   call bar
                         # call function, return val in %eax
   ## Tear down for function call bar()
   movl %ebp, %esp  # restore stack top: args popped
   ## Continue with function foo()
   addl 5, %eax # add onto answer
   popl %ebp
                        # restore previous base pointer
   ret
```
