CMSC216: x86-64 Control Flow

Chris Kauffman

Last Updated: Wed Mar 26 12:58:36 PM EDT 2025

Logistics

Reading Bryant/O'Hallaron

- Ch 3.6: Control Flow
- ► Ch 3.7: Procedure calls

Goals

- ► RIP: Instruction Pointer
- Jumps and Control flow
- Comparison / TestInstructions
- Procedure calls
- Stack Manipulation

Assignments

- ► Lab07: Stack Manipulation for Procedure Calls
- ► HW07: GDB on Binaries, Stack Smashing
- P3: Due Mon 07-Apr Pre-break Draft version of P3 has had minor typos/bugs fixed and is now finalized

Announcements

Midterm Feedback Posted

- Linked at the bottom of the course schedule
- Responses for some free-form feedback is given
- ► Thanks to all that provided feedback

Control Flow in Assembly and the Instruction Pointer

Instruction Pointer Register

- %rip: special register (not general purpose) referred to as the Instruction Pointer or Program Counter
- %rip contains main memory address of next assembly instruction to execute
- After executing an instruction, %rip automatically updates to the subsequent instruction
 OR in a Jump instruction, %rip changes non-sequentially
- ▶ Do not add/subtract with %rip via addq/subq: %rip automatically updates after each instruction

Jump Instructions

- ► **Labels** in assembly indicate jump targets like .LOOP:
- Unconditional Jump: always jump to a new location by changing %rip non-sequentially
- Comparison / Test: Instruction, sets EFLAGS bits indicating relation between registers/values (greater, less than, equal)
- ➤ Conditional Jump: Jumps to a new location if certain bits of EFLAGS are set by changing %rip non-sequentially; otherwise continues sequential execution

Exercise: Loop Sum with Instruction Pointer (rip)

- Can see direct effects on rip in disassembled code
- rip increases corresponding to instruction length
- Jumps include address for next rip

```
// C Code equivalent
long sum=0, i=1, lim=100;
while(i<=lim){
   sum += i;
   i++;
}
return sum;</pre>
```

```

                                    # rip 61c -> return address
```

Disassembling Binaries

- Binaries hard to read on their own
- ▶ Many tools exist to work with them, notably objdump on Unix
- Can disassemble binary: show "readable" version of contents

```
>> gcc -Og loop.s
                               # COMPTLE AND ASSEMBLE
>> file a.out
a.out: ELF 64-bit LSB pie executable, x86-64, version 1 (SYSV).
>> objdump -d a.out
                              # DISASSEMBLE BINARY
         file format elf64-x86-64
a.out:
Disassembly of section .text:
. . .

```

FLAGS: Condition Codes Register

- Most CPUs have a special register with "flags" for various conditions: each bit is True/False for a specific condition
- ► In x86-64 this register goes by the following names

| Name | Width | Notes | |
|--------|--------|---------------------------------|--|
| FLAGS | 16-bit | Most important bits in first 16 | |
| EFLAGS | 32-bit | Name shown in GDB | |
| RFLAGS | 64-bit | Not used normally | |

▶ Bits in FLAGS register are **automatically** set based on results of other operations like addition / subtraction / etc.

| Bit | Abbrev | Name | Description |
|-----|--------|----------------|---|
| 0 | CF | Carry flag | Set if last op caused Unsigned overflow |
| 6 | ZF | Zero flag | Set if last op yielded a 0 result |
| 7 | SF | Sign flag | Set if last op yielded a negative |
| 8 | TF | Trap flag | Used by gdb to stop after one ASM instruction |
| 9 | IF | Interrupt flag | 1: handle hardware interrupts, 0: ignore them |
| 11 | OF | Overflow flag | Set if last op caused SIGNED overflow/underflow |

Comparisons and Tests

Set the EFLAGS register by using comparison instructions

| Name | Instruction | Examples | Notes |
|---------|-------------|-----------------|----------------------|
| Compare | cmpX B, A | cmpl \$1,%eax | Like if(eax > 1){} |
| | Like: A - B | cmpq %rsi,%rdi | Like if(rdi > rsi){} |
| Test | testX B, A | testq %rcx,%rdx | Like if(rdx & rcx){} |
| | Like: A & B | testl %rax,%rax | Like if(rax){} |

- Immediates like \$2 must be the first argument B
- ▶ B,A are NOT altered with cmp/test instructions
- ► EFLAGS register IS changed by cmp/test to indicate less than, greater than, 0, etc.

Jump Instruction Summary

All control structures implemented using combination of Compare/Test + Jump instructions.

| Instruction | Jump Condition | FLAGS |
|-------------|---------------------------|----------------------|
| jmp LAB | Unconditional jump | - |
| je LAB | Equal / zero | ZF |
| jz LAB | | ZF |
| jne LAB | Not equal $/$ non-zero | ! ZF |
| jnz LAB | | ! ZF |
| js LAB | Negative ("signed") | SF |
| jns LAB | Nonnegative | !SF |
| jg LAB | Greater-than signed | !(SF xor OF) and !ZF |
| jge LAB | Greater-than-equal signed | !(SF xor OF) |
| jl LAB | Less-than signed | (SF xor !OF) |
| jle LAB | Less-than-equal signed | (SF xor !OF) or !ZF |
| ja LAB | Above unsigned | !CF and !ZF |
| jae LAB | Above-equal unsigned | !CF |
| jb LAB | Below unsigned | CF and !ZF |
| jbe LAB | Below-equal unsigned | CF |
| jmp *OPER | Unconditional jump to | - |
| | variable address | |
| | | |

Examine: Compiler Comparison Inversion

- Often compiler inverts comparisons
- i < n becomes cmpX /
 jge (jump greater/equal)</pre>
- i == 0 becomes cmpX /
 jne (jump not equal)
- This allows "true" case to fall through immediately
- Depending on structure, may have additional jumps
 - if(){ .. } usually has a single jump
 - if(){} else {} may have a couple

```
## Assembly translation of
## if(rbx >= 2){
  rdx = 10:
## }
## else{
## rdx = 5:
## }
## return rdx;
  cmpq $2,%rbx # compare: rbx-2
                   # goto less than
        .LESSTHAN
 ## if(rbx >= 2){
 movq $10,%rdx
                   # greater/equal
 ## }
  qmj
        . AFTER
. LESSTHAN:
 ## else{
 movq $5,%rdx # less than
  ## }
. AFTER:
 ## rdx is 10 if rbx >= 2
 ## rdx is 5 otherwise
 movq %rdx,%rax
 ret.
```

Logical And / Or in Assembly

Logical boolean operators like a && b and x || y translate sequences of compare/test instructions followed by conditional jumps. See andcond_asm.s and nestedcond_asm.s

```
// andcond.c
int andcond(int edi){
  int ecx;
  if(edi >= 2 && edi <= 10){
    ecx = 10;
  }
  else{
    ecx = 5;
  }
  return ecx;
}</pre>
```

C Boolean expressions may "short circuit": never execute code associated with later parts of the condition if early part resolves conditional

```
### andcond asm.s
.text
.global andcond
andcond:
 cmpl $2,%edi # compare: edi-2
 il .ELSE
 cmpl $10, %edi # compare: edi-10
 ig .ELSE
 ## if(edi >= 2 && edi <= 10){
 movl $10,%ecx # greater/equal
 ## }
       . AFTER
 qmj
.FLSE:
 ## else{
 movl
       $5,%ecx # less than
 ## }
. AFTER:
 movl %ecx.%eax
 ret.
```

Exercise: The test Instruction

```
main:
            movl
                      $0, %eax
            movl
                      $5,%edi
            movl
                      $3,%esi
                     $0, %rdx
            mova
                     $-4,%ecx
            movl
7
                      %edi.%edi
8
            test1
9
            jnz
                      . NONZERO
10
            add1
                      $20, %eax
11
12
    . NONZERO:
13
            testl
                      %esi,%esi
                      FALSEY
14
            iz
            addl
                      $30, %eax
15
16
    .FALSEY:

                      . ISNULL
19
            jе
                      $40, %eax
            add1
20
21
22
23
            testl
                      %ecx,%ecx
                      NONNEGATIVE
24
            ins
            addl
                      $50, %eax
25
26
27
    . NONNEGATIVE:
```

ret.

28

- ► test1 %eax,%eax uses bitwise AND to examine a register
- Selected by compiler to check for zero, NULL, negativity, etc.
- ► Followed by je / jz / jne / jnz / js / jns
- Trace the execution
- Determine final value in %eax
- Will demo jmp_tests_asm.s in GDB to show how EFLAGS changes

Answers: The test Instruction

```
1 ### From imp tests asm commented.s
                                                                                    // Rough C translation is
                                                                                    if(edi == 0){

34
           ret
                         ## eav is return value
```

cmov Family: Conditional Moves

- Instruction family which copies data conditioned on FLAGS¹
- Can limit jumping in simple assignments

```
cmpq %r8,%r9
cmovge %r11,%r10 # if(r9 >= r8) { r10 = r11 }
cmovg %r13,%r12 # if(r9 > r8) { r12 = r13 }
```

- Note flags set on all Arithmetic Operations
- cmpX is like subQ: both set FLAG bits the same
- Greater than is based on the SIGN flag indicating subtraction would be negative allowing the following:

```
subq %r8,%r9 # r9 = r9 - r8
cmovge %r11,%r10 # if(r9 >= 0) { r10 = r11 }
cmovg %r13,%r12 # if(r9 > 0) { r12 = r13 }
```

 $^{^1}$ Other architectures like ARM have conditional versions of many instructions like addlt r1, r2, r3; RISC V ditches the FLAGS register in favor of jumps based on comparisons like BLT x0, x1, LOOP

Procedure Calls

Have seen basics so far:

```
main:
    call my_func # call a function
    ## arguments in %rdi, %rsi, %rdx, etc.
    ## control jumps to my_func, returns here when done
    ...

my_func:
    ## arguments in %rdi, %rsi, %rdx, etc.
    ...
    movl $0,%eax # set up return value
    ret # return from function
    ## return value in %rax
    ## returns control to wherever it came from
```

Need several additional notions

- Control Transfer to called function?
- Return back to calling function?
- Stack alignment and conventions
- Register conventions

Procedure Calls Return to Arbitrary Locations

- call instructions always transfer control to start of return_seven at line 4/5, like jmp instruction which modifies %rip
- ret instruction at line 6 must transfer control to different locations
 - 1. call-ed at line 11 ret to line 12
 - 2. call-ed at line 17 ret to line 18

ret cannot be a normal jmp

➤ To enable return to multiple places, record a Return Address when call-ing, use it when ret-urning

```

call / ret with Return Address in Stack

call Instruction

- Push the "caller" Return Address onto the stack Return address is for instruction after call
- Change rip to first instruction of the "callee" function

ret Instruction

- Set rip to Return Address at top of stack
- 2. Pop the Return Address off to shrink stack

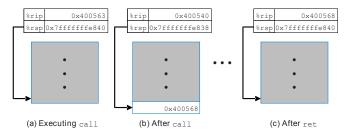

Figure: Bryant/O'Hallaron Fig 3.26 demonstrates call/return in assembly

return_seven_asm.s 1/2: Control Transfer with call

```
### BEFORE CALL

   0x55555555514f <main+16>
                                          %eax.%esi
                                   mov
(gdb) print $rsp --> $3 = 0x7ffffffffe450
```

Warning: %rsp is important for returns

- When a function is about to return %rsp MUST refer to the memory location of the return address
- ret uses value pointed to %rsp as the return address
- Segmentation Faults often occur if %rsp is NOT the return address: attempt to fetch/execute instructions out of bounds
- Stack is often used to store local variables, stack pointer %rsp is manipulated via pushX / subq instructions to grow the stack.
- ▶ Before returning MUST shrink stack and restore %rsp to its original value via popX / addq instructions
- ► There are computer security issues associated stack-based return value we will discuss later

Messing up the Return Address

```
### return_seven_buggy_asm.s
.text
.global return_seven
return seven:
  pushq $0x42 # push but no pop before returning
  movl $7. %eax
                    # %rsp points to a 0x42 return address - BAD!
  ret
 REG | VALUE |
                   | ADDRESS | VALUE | NOTE
                 |-----
                   | 0x77128 | 0x554210 | Ret Address
l rax l
| rsp | 0x77120 |--->| 0x77120 | 0x42 | Pushed Val |
> gcc -g return_seven_buggy_asm.s
> ./a.out
Segmentation fault (core dumped) ## definitely a memory problem
> valgrind ./a.out
                                ## get help from Valgrind
==2664132== Jump to the invalid address stated on the next line
==2664132==
             at 0x42: ???
                                ## execute instruction at address 0x42??
==2664132== by 0x109149: ??? (return seven buggy asm.s:18)
==2664132== Address 0x42 is not stack'd, malloc'd or (recently) free'd
```

Valgrind reports like this often indicate failure to restore the stack pointer as

happened here. If the stack grows, shrink it before returning.

Stack Alignment

- ► According to the strict x86-64 ABI, must align rsp (stack pointer) to 16-byte boundaries when calling functions
- ▶ Will often see arbitrary pushes or subtractions to align
 - Functions called with 16-byte alignment
 - call pushes 8-byte Return Address on the stack
 - ▶ At minimum, must grow stack by 8 bytes to call again
- rsp changes must be undone prior to return

► Skipping stack alignment works on some machines and breaks on others due to differing processor internals

"I passed all the tests on GRACE but a bunch failed on Gradescope! What gives?"

- Common lament of past students

x86-64 Register/Procedure Convention

- ▶ Used by Linux/Mac/BSD/General Unix
- ▶ Params and return in registers if possible

Parameters and Return

```
RetVal rax / eax / ax / al
Arg 1 rdi / edi / di / dil
Arg 2 rsi / esi / si / sil
Arg 3 rdx / edx / dx / dl
Arg 4 rcx / ecx / cx / cl
Arg 5 r8 / r8d / r8w / r8b
Arg 6 r9 / r9d / r9w / r9b
Arg 7 Push into the stack
Arg 8 Push into the stack
```

C function prototype indicates number, order, type of args so it is known which registers args will be in

Caller/Callee Save

rax rcx rdx rdi rsi r8 r9 r10 r11 # 9 regs

Caller save registers: alter freely

Callee save registers: must restore these before returning

rbx rbp r12 r13 r14 r15

Stack Pointer: special considerations discussed in detail

rsp # 1 reg

6 regs

Caller and Callee Save Register Mechanics

```
main:
            # main: the calleR
   movg $21, %rdi # calleR save arg 1
   movq $31, %rsi # calleR save arg 2
   movq $41, %r10 # calleR save
   movq $7, %rbx # calleE save
   movq $11, %r12 # calleE save
   call foo # foo: the calleE
            %rdi | calleR save arg 1 |
         | %rsi | calleR save arg 2
   ##
         | %r10 | calleR save
   ##
            %rbx | calleE save
       11 | %r12 | calleE save
   cmpq $21, %rdi # unpredictable
   cmpq $7, %rbx # predictably equal
   # main MUST restore %rbx and %r12 to
   # original values as function above
   # main() expects them to be unchanged
```

CalleR Save Regs

May all change across function call boundaries.
Not a problem for **Leaf Functions** which do not call any other funcs

CalleE Save Regs

Have the same values in them after a function call Using them requires saving their original values in the stack and restoring them

sumrange_asm.s

Full example of callee save regs like sumrange_c.c

Pushing and Popping the Stack

pushX data

pushq %rax

- ▶ If local variables or callee save regs are needed on the stack, can use push / pop for these
- ► Push and Pop Instructions are compound: manipulate %rsp and move data in single instruction

Grow Stack, store data at top

Like: subq \$8, %rsp; movq %rax, (%rsp)

```
pushl $25
                      Like: subq $4,%rsp; movq $25, (%rsp)
        popX data
                     Shrink Stack, restore data from it
        popl %edi
                      Like: movl (%rsp), %edi; addq $4, %rsp;
        popq %rax
                      Like: movq (%rsp), %rax; addq $8, %rsp;
main:
    pushq
            %rbp
                             # save register, aligns stack
                             # like subq $8, %rsp; movq %rbp,(%rsp)
                             # call function
    call
            sum_range
    Tvom
            %eax, %ebp
                             # save answer
    . . .
    call
            sum_range
                             # call function, ebp not affected
            %rbp
                             # restore rbp, shrinks stack
    popq
                             # like movq (%rsp), %rbp; addq $8, %rsp
    ret
```

Exercise: Local Variables which need an Address

Compare code in files

- swap_pointers.c : familiar C code for swap via pointers
- swap_pointers_asm.s : hand-coded assembly version

Determine the following

- 1. Where are main() local variables x,y stored in assembly?
- 2. Where does the assembly version "grow" the stack?
- 3. How are the values in main() passed as arguments to swap_ptr()?
- 4. Where are swap_ptr() local variables stored in assembly?
- 5. Where does the assembly version "shrink" the stack?

Exercise: Local Variables which need an Address.

- Where are main() local variables x,y stored in assembly?
- Where does the assembly version "grow" the stack?
- 3. How are the values in main() passed as arguments to swap_ptr()?
- 4. Where are swap_ptr() local variables stored in assembly?
- 5. Where does the assembly version "shrink" the stack?

```
1 // swap pointers.c
2 #include <stdio.h>
3
4 void swap ptr(int *a, int *b){
    int tmp = *a;
5
    *a = *b:
    *b = tmp:
8
    return;
9 }
10
11 int main(int argc, char *argv[]){
12
    int x = 19;
13
    int y = 31;
    swap ptr(&x, &y);
14
15
    printf("%d %d\n",x,y);
    return 0:
16
17 }
```

```
# swap pointers asm.s
 2 .text
   .global swap_ptr
   swap_ptr:
                    (%rdi), %eax
 5
            movl
           movl
                    (%rsi), %edx
 7
           movl
                    %edx. (%rdi)
 8
           movl
                    %eax. (%rsi)
            ret
   .global main
11
   main:
12
                    $8, %rsp
            subq
13
           movl
                    $19, (%rsp)
                    $31, 4(%rsp)
           movl
14
                    %rsp, %rdi
           mova
15
            leag
                    4(%rsp), %rsi
16
17
            call
                    swap_ptr
18
            leag
                     .FORMAT(%rip), %rdi
19
20
           movl
                    (%rsp), %esi
                    4(%rsp), %edx
21
           movl
                    $0. %eax
22
           movl
23
            call.
                    printf@PLT
24
25
            addq
                    $8, %rsp
                    $0. %eax
26
            movl
27
            ret
28 data
   . FORMAT:
30
            .asciz "%d %d\n"
```

Answers: Local Variables which need an Address

- 1. Where are main() local variables x,y stored in assembly?
- 2. Where does the assembly version "grow" the stack?
- 3. How are the values in main() passed as arguments to swap_ptr()?

- 4. Where are swap_ptr() local variables stored in assembly? Stored entirely in registers; args %rdi,%rsi are a,b while tmp is spread across regs %eax,%edx
- 5. Where does the assembly version "shrink" the stack?

```
addq $8, %rsp # shrink stack by 8 bytes movl $0, %eax # set return value ret
```

Diagram of Stack Variables

- Compiler determines if local variables go on stack
- ▶ If so, calculates location as rsp + offsets

```
1 // C Code: locals.c
                                       REG

11
     addq
             $24, %rsp
```

Summary of Procedure Calls: ABC() calls XYZ()

ABC() Caller callq XYZ # ABC to XYZ
XYZ() Callee retq # XYZ to ABC

- ABC() "saves" any Caller Save registers it needs by either copying them into Callee Save registers or pushing them into the stack
- ABC() places up to 6 arguments in %rsi, %rdi, %rdx, ..., remaining arguments in stack
- ABC() ensures that stack is "aligned": %rsp contains an address that is evenly divisible by 16
- 4. ABC() issues the callq ABC instruction which (1) grows the stack by subtracting 8 from %rsp and copies a return address to that location and (2) changes %rip to the staring address of func
- 5. XYZ() now has control: %rip points to first instruction of XYZ()
- XYZ() may issue pushX val instructions or subq N,%rsp instructions to grow the stack for local variables
- XYZ() may freely change Caller Save registers BUT Callee Save registers it changes must be restored prior to returning.
- XYZ() must shrink the stack to its original position via popX %reg or addq N,%rsp instructions before returning.
- 9. XYZ() sets %rax / %eax / %ax to its return value if any.
- 10. XYZ() finishes, issues the retq instruction which (1) sets the %rip to the 8-byte return address at the top of the stack (pointed to by %rsp) and (2) shrinks the stack by doing addq \$8,%rsp
- 11. ABC() function now has control back with %rip pointing to instruction after call XYZ; may have a return value in %rax register
- 12. ABC() must assume all Caller Save registers have changed

History: Base Pointer rbp was Previously Special Use

- ➤ 32-bit x86 / IA32 assembly used rbp and rsp to describe stack frames
- int bar(int, int, int);
 int foo(void) {
 int x = bar(1, 2, 3);
 return x+5;
 }
 - All function args pushed onto the stack when calling, changes both rsp and rbp
 - ➤ x86-64: optimizes rbp to general purpose register, occasionally used for stack purposes

```
# Old x86 / IA32 calling sequence: set both %esp and %ebp for function call
# Push all arguments into the stack
foo:
   pushl %ebp
             # modifying ebp, save it
   ## Set up for function call to bar()
   movl %esp,%ebp
                       # new frame for next function
                        # push all arguments to
   pushl 3
   pushl 2
                        # function onto stack
   pushl 1
                       # no regs used
   call bar
                        # call function, return val in %eax
   ## Tear down for function call bar()
   ## Continue with function foo()
   addl 5,%eax
                        # add onto answer
   popl %ebp
                        # restore previous base pointer
   ret
```
