ID#: X.500: Name:

CSCI 2021: Practice Final Exam

Fall 2021

University of Minnesota

20 minutes Exam period:

Points available:

Background: Nearby are several C files along with two attempts to compile them on the left. Study these and answer the questions that follow.

```
1 > gcc vf_weak_var.c vf_strong_func.c vf_main.c
                                                    # COMPILE 1
                                                                                     1 // FILE: vf_main.c
2 /usr/bin/ld: warning: size of symbol 'foo' changed from 4 to 14
                                                                                     2 #include <stdio.h>
_{\rm 3} /usr/bin/ld: warning: type of symbol 'foo' changed from 1 to 2
                                                                                     3 int foo(int x);
                                                                                     4 int main(){
5 a.out: ELF 64-bit LSB pie executable, x86-64, version
                                                                                         printf("%d\n",foo);
                                                                                         printf("%d\n",foo(2));
6 > ./a.out
7 -573193927
                                                                                         return 0;
                                                                                     8 }
8 4
9 > rm a.out
                                                                                     10 // FILE: vf_strong_func.c
10
11 > gcc vf_strong_var.c vf_strong_func.c vf_main.c # COMPILE 2
                                                                                    11 int foo(int x){
12 /usr/bin/ld: multiple definition of 'foo';
                                                                                         return 2*x;
                                                                                    12
13 collect2: error: ld returned 1 exit status
                                                                                    13 }
14 > file a.out
                                                                                     14
15 a.out: cannot open 'a.out' (No such file or directory)
                                                                                     15 // FILE: vf_strong_var.c
                                                                                     16 int foo = 0;
  Problem 1 (10 pts):
                             Why does COMPILE 1 succeed while COMPILE 2
                                                                                     18 // FILE: vf_weak_var.c
  fails? Mention pertinent properties of ELF files in your answer.
```

Problem 2 (10 pts): Nearby is the output of pmap showing page table virtual memory mapping information for a running program called memory_parts. Answer the following questions about this output.

- (A) The mapped memory references something called libc-2.26.so. Describe this entity and what kind of information you would expect to find at the mapped locations.
- (B) Why does pmap only show a limited number of virtual addresses? What would happen if the program attempted to access an address not listed in the output? Example: address 0x00 is not in the listing.

```
> pmap 7986
7986:
        ./memory_parts
00005579a4abd000
                      4K r-x-- memory_parts

```

19 int foo;

Problem 3 (10 pts): We have seen that a common use of mmap() is to map files into the virtual memory space of a program to make it easy for them to processed. However, this is only one of the uses for mmap() which is a fundamental tool for programs to interact with the Operating System and hardware. The Loader is the program which will take the disk image of a program like a.out and load it into memory to run. Discuss how mmap() can be used by the loader to place the required sections of ELF files in memory and establish areas such as the Stack and Heap for that program. In this, mention what important data structure about a program mmap() manipulates.

Problem 4 (10 pts): New programmers are often surprised to learn that once an array is allocated, its size cannot be extended. In C code, this is easily observable as calling malloc(16) will yield a block of 16 bytes but there are no simple calls to expand this block of memory. Consider a proposed function for EL Malloc called int el_expand_block(el_blockhead_t *bock) which would expand a given block.

- (A) What conditions need to occur to for the function to succeed?
- (B) Why is it impossible to expand a block in some cases?
